Re:

Revised Phase I Corrective Measures Study Report

Refined Metals Facility Beech Grove, Indiana IND 000 718 130

Dear Mr. Adenuga,

Please find enclosed the revised Phase I Corrective Measures Study Report that has been prepared in response to EPA compents.

I certify under penalty of perjury that the information contained in or accompanying the enclosed revised Phase I Corrective Measures Study Report is, to the best of my knowledge after thorough investigation, true, accurate, and complete. I am aware that there are significant penalties for submitting false information, including the possibility of fine and imprisonment for knowing violations.

Sincerely,

REFINED METALS CORPORATION

Matthew A. Love

- Corrective Measures Study Activities Summary Report Baseline Human Health Risk Assessment 1
- 2

1.0 INTRODUCTION

Presented herein, is the revised Phase I Corrective Measures Study (CMS) Report for the Refined Metals Corporation (RMC) facility in Beech Grove, Indiana. Pursuant to the CMS Work Plan, approved by USEPA in a letter dated November 5, 2003, this report has been prepared to present the results of the additional sampling activities and the preliminary risk assessment results. The original version was submitted on June 22, 2004. This submission has been revised to reflect the comments made by the USEPA in a letter dated January 18, 2005. This revision also includes changes made in response to USEPA comments in a letter dated August 17, 2004 and communications between USEPA and Refined subsequent to the January 18, 2005 letter. A description of the activities is provided in the following sections. Copies of the revised CMS Activities Summary Report and revised Baseline Human Health Risk Assessment are provided as attachments.

2.0 FIELD ACTIVITIES

Based on an evaluation of previous investigation results following the Phase II RCRA Facility Investigation (RFI), a determination was made that additional characterization sampling was required for sediment and groundwater at the RMC Site. The sediment sampling consisted of collecting additional samples from the drainage ditch along the CSX Transportation railroad right-of-way north of the facility and from the grass lined drainage ditch along the west side of Arlington Avenue. Sediment samples were collected from six locations along the railroad drainage ditch and four locations in the Arlington Avenue drainage ditch. Two samples were collected at each location. Along Arlington Avenue, one sample was collected from the 0 to 6inch depth and the second from the 6 to 12-inch depth. Along the railroad right-of-way, they were collected from 0 to 3 inches and 3 to 10 inches. The depth of the railroad samples was consistent with the requirements for soil samples, although they were intended to be consistent with the 0 to 6-inch and 6 to 12-inch depths for sediment samples. The change in depth was inadvertent and was not detected until review of sampling logs after the completion of sampling. For the metals included in the analysis, the shallower depths likely provide higher concentrations in the 0 to 3-inch and 3 to 10-inch samples when compared to a 0 to 6-inch sample or 6 to 12inch sample, respectively, from the same location,

Groundwater sampling included the installation of three piezometers in the area north and east of the former manufacturing area. The piezometers were installed with the intent of further refining groundwater flow direction prior to selection of locations for the new monitoring wells. The piezometers were allowed to set for 24 hours before groundwater level measurements were taken from the existing shallow monitoring wells at the north end of the former manufacturing area and the piezometers. Groundwater flow direction was re-assessed based on the measurements and the locations for two new groundwater-monitoring wells were selected. The new groundwater monitoring wells were installed using hollow stem auger (HSA) drilling techniques. The piezometers were abandoned after groundwater level measurements were taken. Groundwater

samples were collected from all the Site groundwater monitoring wells between October 26 and 28, 2003 using low flow sample collection techniques.

A complete description of the sediment and groundwater sampling activities is provided in the revised Phase I CMS Activities Summary Report which is provided as Attachment 1 to this report. No changes were made to the Phase I CMS Activities Summary Report since submission of the October 12, 2004 submission.

3.0 ANALYTICAL RESULTS

3.1 GROUNDWATER

Shallow groundwater at the Site is perched and discontinuous and is not used for any purpose. Groundwater samples collected from the shallow groundwater monitoring wells in the north end of the former manufacturing area (MW-2, 7 and 8) gave unfiltered results for total lead in excess of the Indiana Department of Environmental Management (IDEM) Residential Default RISC Criteria (15 ug/L). Analysis of filtered groundwater samples from those wells for lead from the same sampling event were at or below the IDEM Residential Default RISC Criteria. Filtered and unfiltered results for arsenic in MW-1, MW-2, MW-7 and MW-8, and unfiltered results only for MW-3, MW-5 and MW-10 were above the background concentration for arsenic (8.5 µg/l) calculated in the Phase II RFI. No other parameters for MW-2, MW-7 and MW-8 or any of the parameters analyzed for any other well on-site exceeded the IDEM Residential Default RISC Criteria.

3.2 <u>SEDIMENT</u>

Concentrations of lead in the shallow surface sediment samples collected at the depth of 0-3 inches ranged from 617 mg/kg to 14,800 mg/kg and concentrations or arsenic ranged from 12 mg/kg to 169 mg/kg at this depth. Concentrations of lead in the shallow surface sediment samples collected at the depth of 0-6 inches ranged from 411 mg/kg to 874 mg/kg and concentrations of arsenic ranged from 11 mg/kg to 12 mg/kg at this depth. The calculated background for arsenic in shallow surface soil (10.5 mg/kg) was exceeded in all samples. The cleanup level for lead calculated in the Human Health Risk Assessment (Attachment 2)(15,916 m/kg) was not exceeded in these samples.

Concentrations of lead in the subsurface sediment samples collected at the depth of 3-10 inches ranged from 403 mg/kg to 15,700 mg/kg and concentrations of arsenic ranged from 9 mg/kg to 216 mg/kg at this depth. Concentrations of lead in the samples collected at the depth of 6-12 inches ranged from 24 mg/kg to 1,470 mg/kg and concentrations of arsenic ranged from 8.3 mg/kg to 15 mg/kg at this depth. The calculated background concentrations for arsenic in subsurface soil (7.9 mg/kg) was exceeded in all samples. The calculated cleanup level for lead (15,916 mg/kg) was not exceeded in these samples.

4.0 PRELIMINARY RESULTS OF RISK ASSESSMENT

Gradient Corporation (Cambridge, MA) conducted the Baseline Human Health Risk Assessment (Risk Assessment) for RMC. Pursuant to the CMS Work Plan, the Risk Assessment evaluated a variety of exposure scenarios for lead and arsenic for workers at the facility and on the adjacent Citizens Gas property. The evaluation determined that the calculated risk for existing arsenic levels at the Site are within the USEPA target risk ranges for the exposure scenarios evaluated. The lead risk evaluation determined that soil lead concentrations in some areas of the Site create a predicted (95% UCL) blood lead >10ug/dl for the construction worker in the "on-site" area, and for the groundskeeper and plant worker in the "grassy area".

Results of the risk assessment for lead include a Preliminary Remediation Goal (PRG) for each of the exposure scenarios which predict a 95% UCL blood lead >10 ug/dl. The model also provides a Remedial Action Level (RAL), which represents the soil cleanup concentration that will result in remaining soil having an average soil lead concentration less than the PRG. The concept of a RAL is consistent with the adult lead model, which recognizes that the model evaluates exposure on an area wide basis. This means that soils with concentrations exceeding 78,900 mg/kg must be remediated in the "on-site" area to result in an average lead concentration less than 4,601 mg/kg. For the grassy site area (which also includes the wooded areas), the PRG and RAL are 3,195 and 16,700 mg/kg, respectively. The PRG for the Citizens Gas property is 1,840 mg/kg, which is higher than the average soil lead concentration; therefore, no remediation is necessary on the Citizens Gas property.

The complete Baseline Human Health Risk Assessment report is provided as Attachment 2.

5.0 CONCLUSION

Based on the results of the Risk Assessment, risk estimated for arsenic fall within the USEPA target risk range and the ptotal hazard index are all well below 1.0. Based on this analysis, no soil remediation is believed to be necessary for arsenic.

A conclusion of the Baseline Human Health Risk Assessment is that soil remediation is necessary in the "on-site" plant area to remove subsurface soil with total lead concentrations that exceed the calculated RAL of 78,900 mg/kg. Because the exposure scenario assumes a worker who is performing intrusive activities, this standard is being applied to areas with and without pavement.

For the "grass areas", which includes all areas of the site excluding the "on-site" area, the RAL is 16,700 mg/kg for surface soils and no remediation is required for subsurface soils (i.e., soils deeper than 6 inches). Additionally, because the exposure scenario anticipates a non-intrusive use, no removal will be proposed beneath areas of existing pavement. The drainage ditches are considered to be part of the "grass areas" and will therefore be remediated to the 16,700 mg/kg RAL.

Additional sediment sampling is proposed in the drainage ditch that drains around the west side of the Citizens Gas property from the railroad right of way. A description of the proposed sampling is provided in the CMS Activities Summary Report.

- Geoprobe and Monitoring Well Logs Sediment Sampling Data October 2003 Groundwater Data В

1.0 INTRODUCTION

1.1 <u>GENERAL</u>

This Corrective Measures Study Activities Summary Report has been submitted by Advanced GeoServices Corp. (AGC) on behalf of Refined Metals Corporation (RMC). This report presents and discusses the methods and procedures used to implement the scope of work as proposed in the Phase II RCRA Facility Investigation (RFI) Report. Groundwater monitoring well installation and sampling activities were conducted by AGC. These activities consisted of installing three piezometers and two groundwater monitoring wells, groundwater sampling and sediment sampling at on-site and off-site locations. Laboratory sample analysis was performed by TriMatrix Laboratories Inc. (TriMatrix) of Grand Rapids, Michigan.

The RMC facility was the location of secondary lead smelting operations from 1968 through 1995. RMC was involved in the reclamation of lead from used automotive and industrial batteries and other lead bearing materials. The Site ceased smelting operations on December 31, 1995. Additional background and facility operation can be found in the Phase II RCRA Facility Investigation Report, dated November 18, 2002.

During its operational life, the facility handled materials that were classified as hazardous materials or hazardous wastes under the Resource Conservation and Recovery Act (RCRA). At this time, the Site is idle except for the wastewater treatment system which remains in operation. The wastewater treatment system remains in place to collect and treat stormwater runoff from the lined lagoon and other Site areas.

2.0 WELL INSTALLATION ACTIVITIES

2.1 <u>INTRODUCTION</u>

Background and facility operation information can be found in the Phase II RCRA Facility Investigation Report, dated November 18, 2002. During the Corrective Measures Study (CMS) three temporary piezometers and two groundwater monitoring wells were installed by Boart Longyear, Environmental Division, from Greensberg, Indiana. The three piezometers were installed using a truck mounted Geoprobe in the area north and east of the former manufacturing area. The piezometers were installed for the purpose of refining groundwater flow prior to selection of locations to install two new wells. Geoprobe borings were advanced into the shallow perched groundwater and the piezometer was constructed using a one (1) inch diameter PVC 0.010 screen. The piezometers were constructed on September 4, 2003 as follows:

| | Depth of | Depth of | Screen | GW Elevation |
|------|----------|------------|--------|--------------|
| | Boring | Piezometer | Length | 9/05/2003 |
| GP-1 | 20' | 18.0' | 15' | 837.63 |
| GP-2 | 15' | 14.8' | 10' | 839.30 |
| GP-3 | 25' | 23.5' | 15' | 877.89 |

Groundwater level measurements were taken from the existing monitoring wells north of the former manufacturing area and piezometers on September 5, 2003 and the locations for two new groundwater-monitoring wells were selected.

The two groundwater monitoring wells were installed between September 8-10, 2003 and designated as MW-10 and MW-11. Groundwater monitoring well MW-10 is located east of MW-2 within the wooded area as shown on Figure 2-1. The depth of the boring for MW-10 was recorded to be 36 feet below ground surface (bgs). Groundwater monitoring well MW-11 is located approximately 156 feet east of MW-8 along the fence line of Arlington Avenue. The

depth of the boring for MW-11 was measured at 30 feet bgs. The locations of both wells installed are shown on Figure 2-1.

2.1.1 <u>Drilling Methods</u>

The soil borings were advanced using hollow stem auger (HSA) techniques and continuous split spoon samples were collected in accordance with ASTM D 1586. The logs for the borings and well construction completed as part of this investigation are included in Appendix A. The samples recovered from the advancement of the deep borings were logged and described using USCS soil classification.

2.1.2 Groundwater Monitoring Well Construction

The monitoring wells were constructed using a 4-inch ID, flush-threaded, Schedule 40 PVC riser with a 10-foot length of factory-slotted 0.010-inch PVC well screen. A sand pack was placed to 2 feet above the top of the monitoring well screen with No. 5 sand. A minimum 2-foot thick bentonite seal was placed on top of the sand pack.

All monitoring wells were completed with a steel protective casing with a locking cap. The protective casing extends from an approximate depth of 3 feet bgs to approximately 2 feet above ground. A neat cement seal was placed around the protective casing to a depth of 2.5 to 3 feet bgs. A 2-foot square well pad was installed so that the surface slopes away from the well.

2.1.3 Groundwater Monitoring Well Development Method

Each groundwater monitoring well installed as part of this Corrective Measures Study field activities were developed using the surge-block and pump method. Groundwater monitoring wells were first surged using a plunger-type surge block assembly. This provides the necessary turbulence in and immediately surrounding the well screen to remove fine-grained material. The wells were then purged and developed by continuous pumping using a electric submersible

pump. Well development ceased when the development water in each well was relatively sediment free, exhibited a satisfactory visual clarity and yield.

2.2 GROUNDWATER SAMPLING

2.2.1 Groundwater Well Evacuation

Following the installation of the two additional groundwater monitoring wells, groundwater samples were collected. The sampling event took place on October 26-29, 2003. Groundwater samples were obtained from groundwater monitoring wells MW-1, MW-2, MW-3, MW-4, MW-5, MW-6SR, MW-7, MW-8, MW-9, MW-10 and MW-11. A total of 11 groundwater samples were collected at the Site (excluding QA/QC samples). A low-flow sampling technique was employed to more accurately determine the potential for site-related constituents which may have entered the groundwater.

Each groundwater monitoring well was purged using a stainless steel low-flow bladder pump placed at the midpoint of the screen in each well. The wells were purged at a flow rate ranging from 100 to 300 milliliters per minute mls/min, depending on the yield of the well. A flow-through cell was used to measure the following field parameters: pH, temperature, conductivity, redox potential, and dissolved oxygen prior to contact with oxygen. These parameters were collected at 3 to 5 minute intervals during purging event. Turbidity was also measured at the same time interval. The wells were purged until the field parameters stabilize to within 10% over three readings and pH readings differ by less than 0.1 unit.

2.2.2 <u>Groundwater Sample Collection</u>

Once the field parameters had stabilized, samples were collected directly from the pump discharge line into laboratory-supplied bottles containing the necessary preservatives at a sampling flow rate of 100 to 300 mls/min.

Sample containers were labeled with a unique identifying number, time and date of sample collection, requested analysis, preservative, and the initials of the sample collector. Samples were packed on ice and shipped to TriMatrix Laboratories Inc. for analysis of eight RCRA metals and antimony (SW-846 6010). Samples for dissolved metals analyses were field filtered through a dedicated disposable Nalgene 0.45 µm membrane filter immediately after collection and prior to preservation. The sample was decanted into the dedicated, Nalgene disposable filtration unit and filtered under vacuum pressure created by a hand-held pump. The sample was then immediately transferred to a laboratory supplied bottleware.

3.0 SEDIMENT SAMPLING

Sediment samples were collected from four locations along the drainage ditch running parallel to Arlington Avenue and from six locations along the CSX rail line drainage ditch. The samples collected along the Arlington Avenue drainage ditch were designated R2SED-11 through R2SED-14. The samples collected along the CSX line were designated R2SB25 through R2SB-30. The location of the sediment samples are presented on Figure 3-1. The CMS Work Plan specified collection of two sediment samples from each location at depths of 0 to 6 inches and 6 to 12 inches. Along Arlington Avenue, the samples (designated R2SED-11 through R2SED-14) were collected from the 0 to 6-inch depth and the 6 to 12-inch depth as specified for sediment samples. Along the CSX railroad right-of-way, the samples (designated R2SB25 through R2SB-30) were inadvertently collected following the sample intervals utilized for soil sampling of 0 to 3 inches and 3 to 10 inches. The deviation was not identified until after the completion of sampling activities. The data has been retained and presented in this report, however the results are likely biased towards a higher concentration than the intended sample depths would have produced. This is because off-site sediment impacts from facility operations are likely attributable to stormwater runoff and/or air deposition and because metals are not expected to migrate vertically any applicable distance. For this reason, it is expected that impacts from facility operations would be greater near the surface and would relapse rapidly with depth.

The depth of collection was placed as a suffix to each sample location to delineate in which depth the result is correlated. All sediment samples were collected using decontaminated hand augers. The sediment from each interval was thoroughly homogenized in an aluminum mixing pan and was placed directly into a laboratory supplied jar. Each sediment sample was then placed on ice for shipment and was submitted to TriMatrix to be analyzed for arsenic and lead (EPA Method SW-846 6010B).

4.0 RESULTS

4.1 GROUNDWATER

4.1.1 Groundwater Screening

Arsenic and lead are the two site constituents of concern (COCs) that were detected at levels above the concentrations used for initial groundwater screening purposes. A background concentration was calculated for initial screening of arsenic in groundwater. The background concentrations for arsenic in groundwater has been calculated to be $8.5~\mu g/l$, which is the mean concentration taken from MW-9 plus one standard deviation. The current EPA Region 9 Preliminary Remediation Goals for Tap Water do not provide a standard for lead in groundwater; therefore, we are utilizing the Indiana Department of Environmental Management (IDEM) Residential Default RISC criteria of 15 $\mu g/l$. The IDEM Residential Default RISC criteria for arsenic is $50~\mu g/l$.

4.1.2 Groundwater Sampling Results

The analytical results for samples collected from the on-site wells for the groundwater sampling event are presented in Table 4-1. A groundwater surface map is shown as Figure 4-1. October 2003 sample results are provided in Figure 4-2.

Total arsenic was found in groundwater samples at concentrations ranging from 1.3 μ g/l in MW-4 to 290 μ g/l in MW-7. Arsenic concentrations were detected above the background concentration in MW-1 (24 μ g/l), MW-2 (15 μ g/l), MW-3 (28 μ g/l), MW-5 (8.8 μ g/l), MW-7 (290 μ g/l), MW-8 (19 μ g/l) and MW-10 (24 μ g/l). Only MW-7 exceeded the IDEM Residential Default RISC Criteria for arsenic in groundwater.

Total lead was found in groundwater samples at concentrations ranging from below laboratory detection level in MW-1, MW-3, MW-4, MW-10, and MW-11 to 217 μ g/l in MW-7. Lead concentrations were detected above the IDEM Residential Default Risk Criteria concentration in MW-2 (44 μ g/l), MW-7 (217 μ g/l) and MW-8 (55 μ g/l). The only filtered sample at or above 15 μ gl was MW-8 at a concentration of 15 μ gl.

4.2 <u>SEDIMENT</u>

4.2.1 <u>Sediment Screening</u>

Arsenic and lead are the two site constituents of concern (COCs) that were detected at levels above their initial screening levels for soil and sediment. Samples collected from the drainage ditches are referred to as sediment in this report; however, because of the physical character of the material sampled and geomorphic setting, they are compared to the soil standards. The calculated background arsenic in soil concentrations are 10.53 mg/kg for surface soil (0-3 inch) and 7.91 mg/kg (>3 inches) for subsurface soils. Based on the Baseline Human Health Risk Assessment (Attachment 2), the target cleanup level for lead in soil at the Site is 15,916 mg/kg for surface (0-6 inches) soil.

4.2.2 Sediment Sampling Results

The validated analytical results for the sediment samples collected within the drainage ditch along Arlington Avenue and the drainage ditch along the CSX rail line are provided in Table 4-2, and a copy of the validation report is provided in Appendix B.The depth of collection was placed as a suffix to each sample location to delineate to show to which depth the result is correlated.

Concentrations of lead in the samples collected at the depth of 0-3 inches ranged from 617 mg/kg at R2SB25 to 14,800 mg/kg at R2SB29, and concentrations of arsenic ranged from 12 mg/kg at R2SB30 to 169 mg/kg at R2SB26 at this depth. The calculated background concentration for

arsenic was exceeded in all samples. The Baseline Human Health Risk Assessment (HHRA) cleanup level for lead was not exceeded in these samples.

Concentrations of lead in the samples collected at the depth of 0-6 inches ranged from 411 mg/kg at R2SED-12 to 874 mg/kg at R2SED-11, and concentrations of arsenic ranged from 11 mg/kg at R2SED-14 and R2SED-12 to 12 mg/kg at R2SED-11 and R2SED-13 at this depth. Table 4-2 presents lead and arsenic results within this depth interval. The calculated background concentration for arsenic was exceeded in all samples. The HHRA cleanup level for lead was not exceeded in these samples.

Concentrations of lead in the samples collected at the depth of 3-10 inches ranged from 403 mg/kg at R2SB28 to 15,700 mg/kg at R2SB29, and concentrations of arsenic ranged from 9 mg/kg at R2SB30 to 216 mg/kg at R2SB29 at this depth. Table 4-2 presents lead and arsenic results within this depth interval. The calculated background concentration for arsenic was exceeded in all samples. The HHRA cleanup level for lead was not exceeded in these samples.

Concentrations of lead in the samples collected at the depth of 6-12 inches ranged from 24 mg/kg at R2SED-14 to 1,470 mg/kg at R2SED-11, and concentrations of arsenic ranged from 8.3 mg/kg at R2SED-13 to 15 mg/kg at R2SED-11 at this depth. The calculated background concentration for arsenic was exceeded in all samples. The HHRA cleanup level for lead was not exceeded in these samples.

5.0 **SUMMARY**

The following are drawn from the findings of the Corrective Measures Study activities:

Groundwater

- Thin discontinuous zones of higher permeability glacial soils in (sand) clayey silt and silty clay characterize the shallow zone of saturation.
- Potentiometric groundwater maps for the shallow wells indicate a high point in the vicinity of MW-1. Those maps also show a trough in the groundwater surface oriented north-south through MW-8, MW-6SR and MW-4. The presence of the trough is believed to be the result of the discontinuous semi-confined zones of saturated sand or a groundwater mounded created by periodic standing water in the flat lawn area between the paved manufacturing areas and Arlington Avenue.
- Arsenic concentrations exceeded the calculated background concentration in all but four of the samples tested.
- Lead detected above the IDEM Residential Default RISC Criteria is limited to MW-2S (18 μ g/l), MW-7S (217 μ g/l) and MW-8S (28 μ g/l) immediately north of the manufacturing area where elevated soil lead concentrations exist.

Sediment

• Elevated arsenic in sediment in the drainage ditch along the CSX line northeast of the Site indicate that off-site transport of sediment has probably occurred. To further delineate these impacts, additional sediment samples shall be collected from the drainage channel that begins at the rail road right-of-way between RS2B-26 and RS2B-27 and flows across the Citizens Gas property. Nine (9) additional

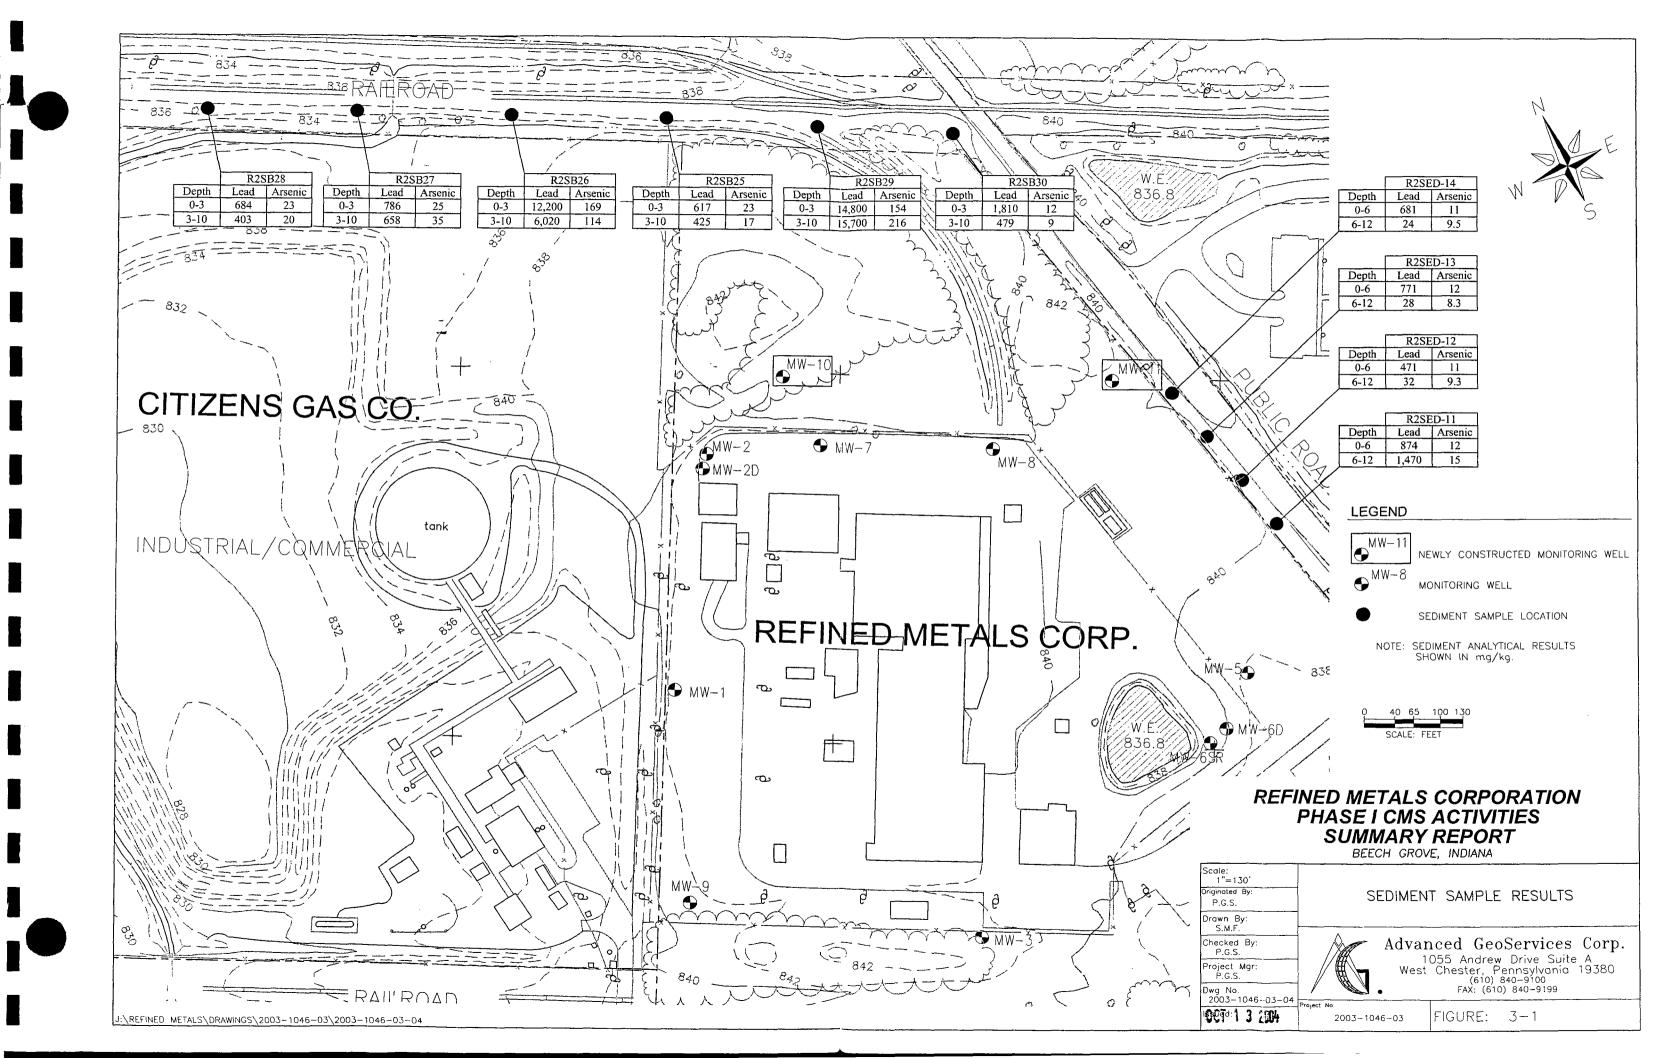

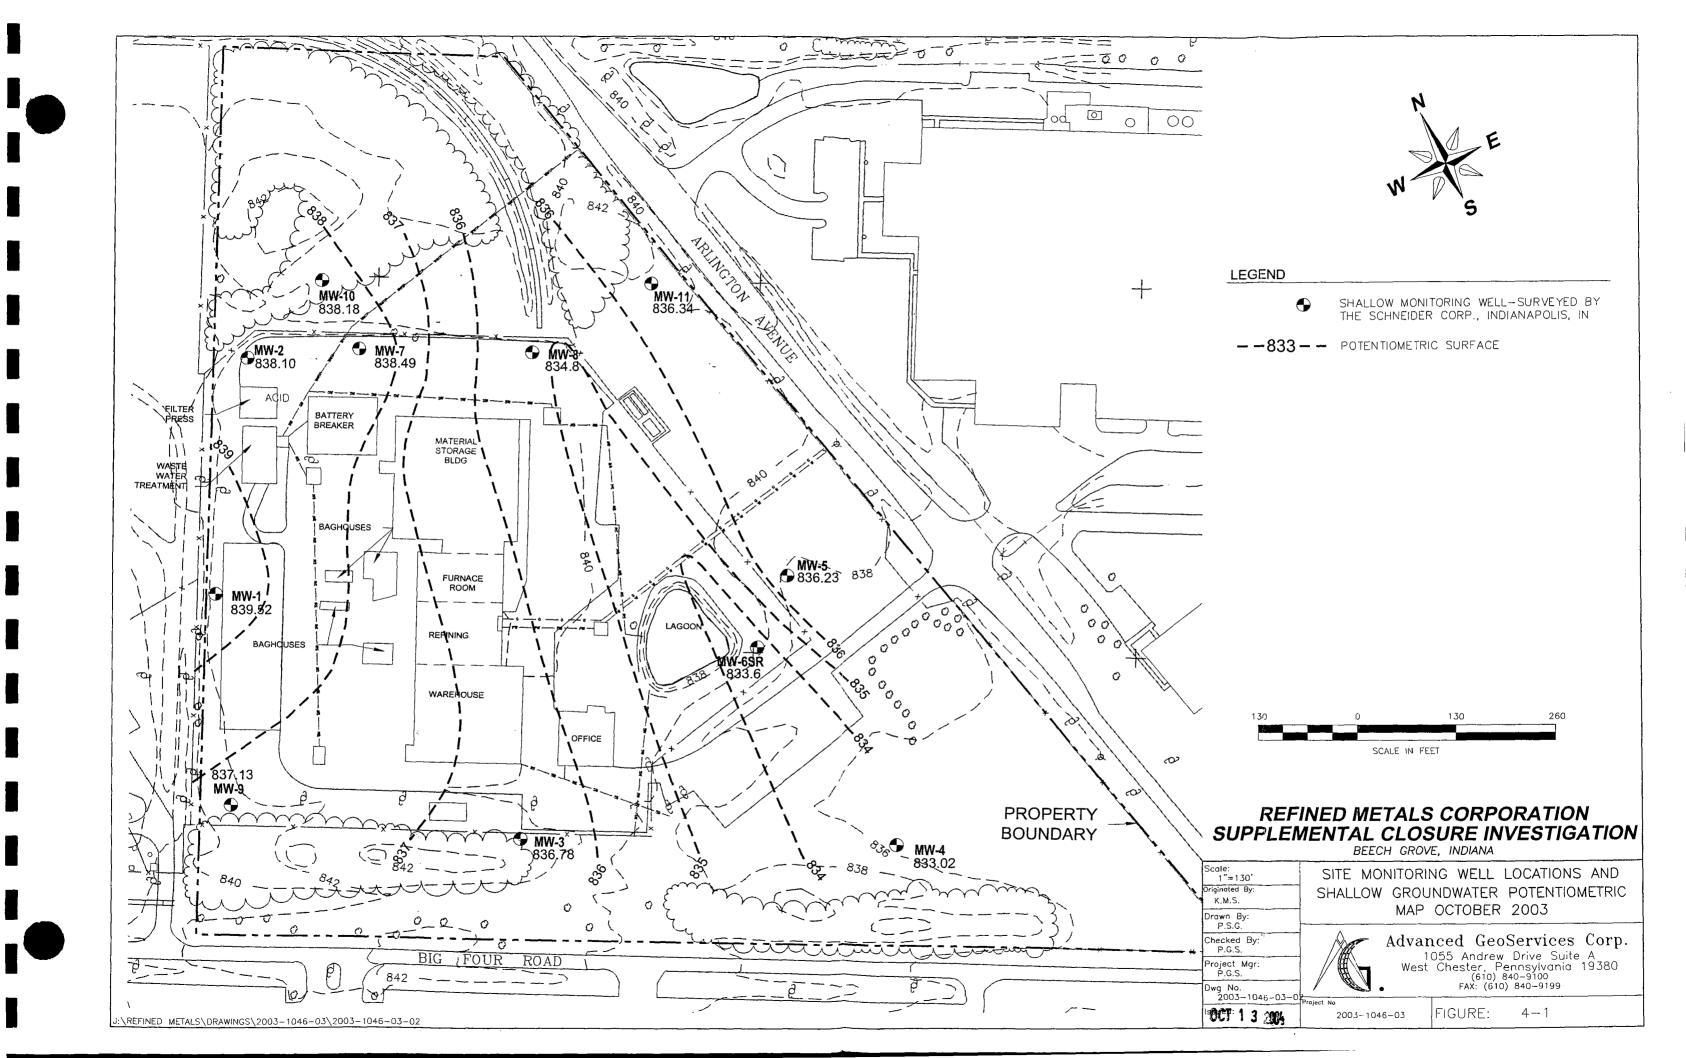

locations will be sampled. Similar to sediment samples previously collected along the CSX line, the samples will be uniformly distributed at approximately 200 feet on-center. Sampling will be performed following the criteria established for sediment samples in the Phase 2 RFI Work Plan.

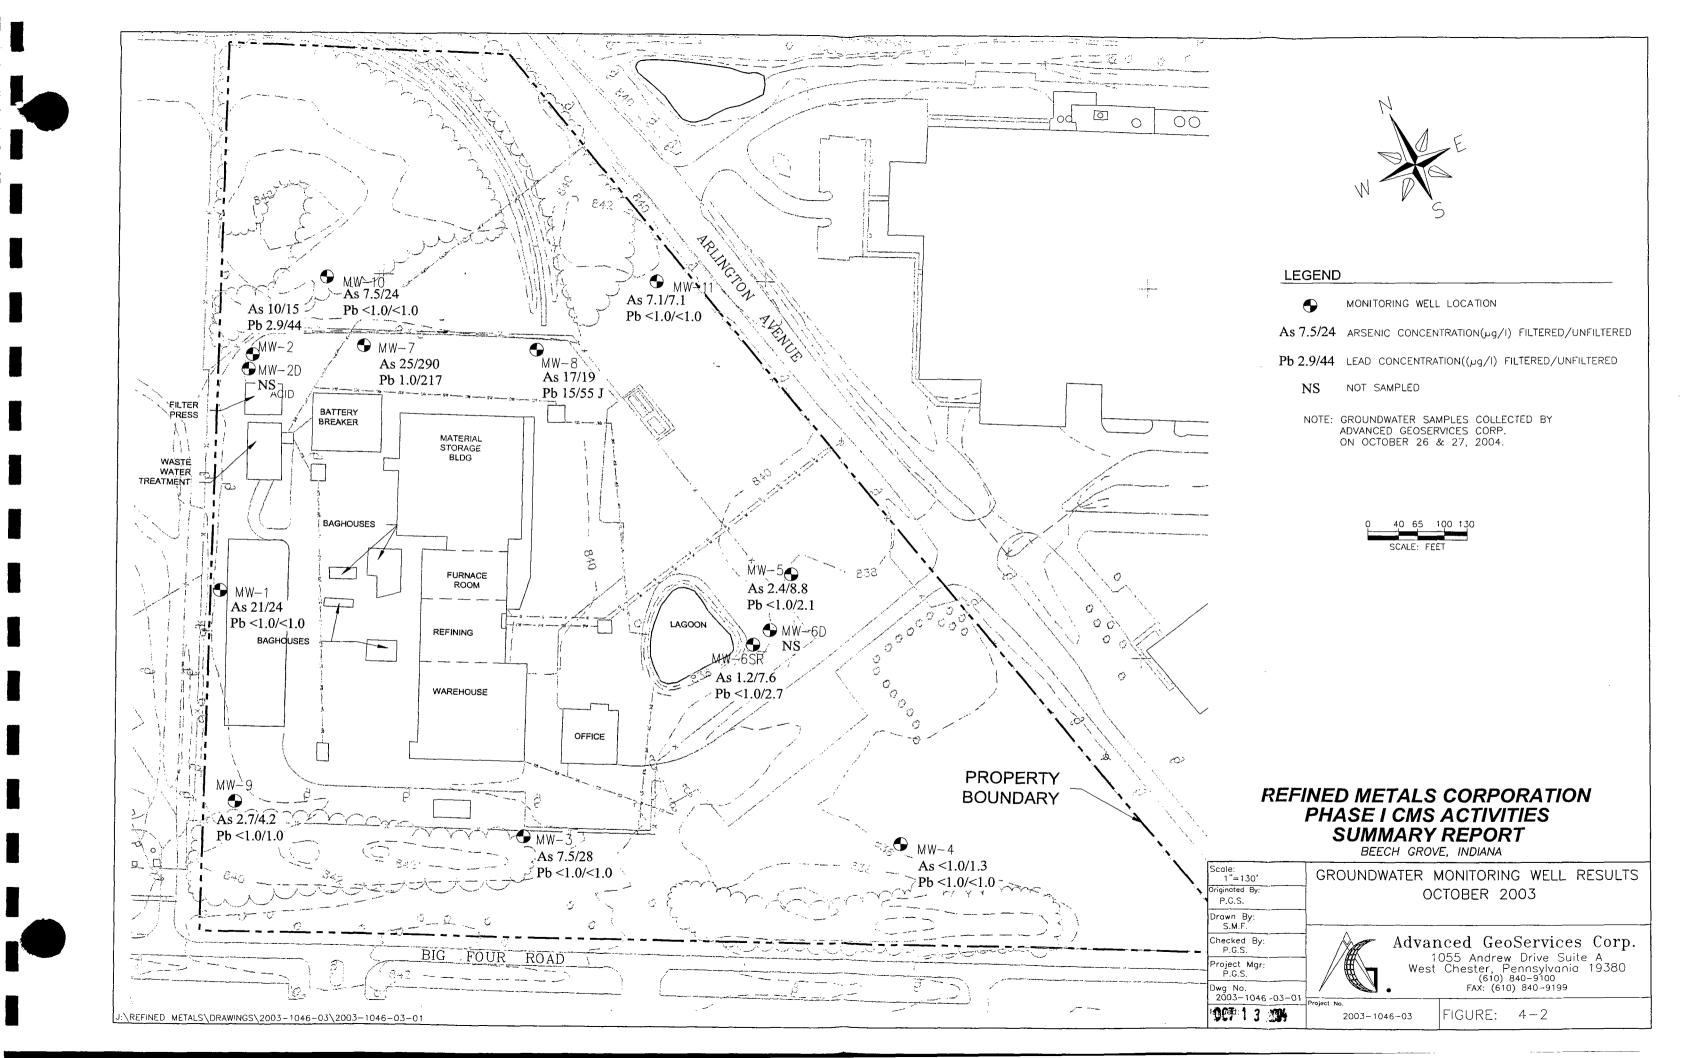

- The most downstream sediment samples from the grass lined swale along Arlington Avenue are below 100 mg/kg total lead. Based on this result no additional sampling is proposed along Arlington Avenue.
- All sediment sample results for lead are shown to be below the RAL calculated in the Baseline Human Health Risk Assessment.

1 Introduction

1.1 Site Description and History

The Refined Metals Corporation (RMC) facility is located at 3700 South Arlington Avenue in Beech Grove, Indiana. Secondary lead smelting and refining operations were conducted at this site from 1968 to the end of 1995.

The site occupies approximately 24 acres, of which approximately 10 acres represented the active manufacturing area (including paved areas and buildings). The remaining 14 acres includes grassed and wooded site areas. The site is bordered by Arlington Avenue to the east, a natural gas facility (Citizen's Gas) to the west, a railroad to the north, and Big Four Road to the south (Figure 1). The site is relatively flat with less than 10 feet of total relief. Natural site drainage is toward the north and east. The former manufacturing area is almost completely paved, and is characterized by nearly 80,000 square feet of structures consisting of the battery breaker, a wastewater treatment plant, material storage areas, a blast furnace, a dust furnace, a metals refining area, warehouse and offices.

A total of five exposure areas were evaluated (Figure 1). One onsite area was the fenced main plant area of the RMC facility, consisting of the plant buildings and surrounding paved areas. The second onsite area was the grassy area to the north, east, and south of the paved facility area. Within the grassy area, the two ditches where sediments were collected (Figure 1) were evaluated separately for certain receptors. Three areas were evaluated offsite: a strip along Arlington Avenue, just outside the eastern border of the RMC facility; the Railroad Ditch along the northern border of the RMC facility, and the Citizen's Gas property to the west of the RMC facility.

1.2 Previous Investigations

On July 14, 1998, RMC entered into a Consent Decree with the United States Environmental Protection Agency (USEPA) and the Indiana Department of Environmental Management (IDEM). Under this Consent Decree, a RCRA Facility Investigation (RFI) was performed to evaluate and determine the nature and extent of releases and to collect information necessary to support risk assessment so that a Corrective Measures Study may be implemented. Pursuant to Section VI, Paragraph 42 of the Consent Decree (Compliance Requirements for Corrective Action), Advanced GeoServices Corp. (AGC) performed the RFI in accordance with an approved RFI work plan on behalf of RMC. The preparation

1 Gradient CORPORATION

and implementation of the RFI work plans were enacted in accordance with Exhibit B of the Consent Decree and the EPA's RCRA Facility Investigation Guidance Document (EPA 530/SW-89-031). The RFI was conducted in multiple phases. The results from the initial phase of sampling were presented in the Phase I RFI Report dated August 31, 2000 (AGC, 2000). Based on the results of the Phase I RFI a Phase II RFI Work Plan was submitted to the EPA on December 20, 2000. In response to comments on the Phase II RFI Work Plan issued by the EPA on April 3, 2001, revisions to the Phase II RFI Work Plan were submitted to the EPA on June 27, 2001. The EPA approved the Phase II RFI Work Plan on July 13, 2001, the results of which were contained in the Final Phase II RFI Report dated February 4, 2003. (AGC, 2003). Additional site sampling was conducted during a closure investigation to address three former RCRA-regulated solid waste managements units (SWMUs). The results of the SWMU closure investigation were presented by AGC in the Closure Investigation Report dated June 1, 2001.

1.3 Report Objectives and Organization

This report presents the results of the baseline human health risk assessment (HHRA) that was conducted to evaluate potential human health risks in each exposure area. The purpose of this evaluation is to determine whether these areas pose any unacceptable health risks or if they require remediation to reduce risk to acceptable levels.

The remainder of this report is organized in the following sections. Section 2 discusses the data used in the risk assessment, and the constituents of potential concern. Section 3 discusses the potential receptors, exposure media, and exposure pathways for each exposure area. Section 4 presents the toxicity assessment. Section 5 presents the risk characterization. Section 6 presents soil lead cleanup levels. Section 7 presents the conclusions for all scenarios evaluated.

2 Constituents of Potential Concern

The results of the Phase I RFI indicated that lead and arsenic are the main contaminants of concern in soil, both onsite and offsite. Lead and arsenic were detected in soil samples from the site at concentrations above both residential and industrial risk-based concentrations (RBCs). The baseline risk assessment retained lead and arsenic as chemicals of potential concern (COPCs) in soil.

3 Exposure Assessment

3.1 Potential Receptors and Exposure Pathways

The potential receptors, exposure media, exposure pathways, and exposure frequencies evaluated in each exposure area are presented in Table 1, and are discussed in more detail below. Exposure Areas are shown in Figure 1.

Table 1
Receptors and Exposure Pathways

| Exposure Area | Media | Depth | Exposure Pathways | Receptors | Exposure Frequency (days/year) | Exposure Duration (years) |
|-------------------------------------|----------------------|--------|---------------------------------|-----------------------|--------------------------------------|---------------------------------|
| | Subsurface soil | 0-5 ft | Ingestion, Dermal Contact | Construction Worker 1 | 50 | 5 |
| Plant Area | | | | Construction Worker 2 | 250 | 1 |
| | | | Comaci | Utility Worker | 10 | 10 |
| · | Soil and | | Ingestion, | Groundskeeper | 50 | 25 |
| | Sediment | 0-6" | Dermal Contact | Future Site Worker | 144 | 25 |
| Grassy Araa | Soil and Sediment | 0-5 ft | Ingestion, | Construction Worker 1 | 50 | 5 |
| Grassy Area | | | Dermal Contact | Construction Worker 2 | 250 | 1 |
| | Sediment | 0-6" | Ingestion, Dermal | Adolescent Trespasser | 21 | 5 |
| | Soil | 0-6" | Contact | Adolescent Trespasser | 21 | 5 |
| Arlington Avenue | Sediment | 0-3" | Ingestion, Dermal Contact | Adolescent Recreator | 42 | 5 |
| Railroad Ditch | Sediment | 0-3" | Ingestion, Dermal Contact | Adolescent Recreator | 42 | 5 |
| Off Site Natural Gas Facility | Surface soil | 0-6" | Ingestion, Dermal Contact | Adult Worker | 225 | 25 |

3.1.1 Facility Area

The plant buildings and surrounding paved areas occupy approximately the central third of the RMC property. The site is largely paved – the only exposed surface soil is limited to a strip along the

western fence line. In this exposure area, we evaluated a utility worker and two types of construction workers who could be exposed to subsurface soil. Both the utility and construction workers are assumed to be exposed to subsurface soil at depths from 0 to 5 feet, *via* incidental ingestion and dermal contact. The utility worker is assumed to have an exposure frequency of 10 days/year and an exposure duration of 10 years. Construction Worker 1 is assumed to have an exposure frequency of 50 days/year for 5 years; this scenario assumes that Exide retains the property, and represents a worker assigned to several small projects per year over a 5 year period. Construction Worker 2 is assumed to have an exposure frequency of 250 days/year for 1 year; this scenario assumes that Exide sells the property, and the property undergoes one year of redevelopment involving subsurface excavation.

3.1.2 Grassy Area North, South, and East of Main Facility

The grassy and wooded areas located north, south, and east of the main facility encompass approximately the northern and southern thirds of the RMC property (Figure 1). The receptors evaluated in both of these areas include an adolescent trespasser and an adult groundskeeper under current use, a future site worker, and two types of construction workers who could be exposed to subsurface soil. A future site worker might be present in the grassy area if the property were sold and the grassy area was not redeveloped. These receptors are assumed to be exposed to soil and/or sediment via incidental ingestion and dermal contact. The adolescent trespasser (age 13-18 years) is assumed to have an exposure frequency of 21 days/year and an exposure duration of 5 years. The groundskeeper is assumed to have an exposure frequency of 50 days/year and an exposure duration of 25 years. A future site worker is assumed to spend most of his time in the plant and surrounding paved areas. However, he may have occasion to visit the grassy/wooded areas for a walk or to eat lunch at a picnic table. The future site worker is assumed to have an exposure frequency in these areas of 4 days/week for 36 weeks/year or 144 days/year, and an exposure duration of 25 years. Construction Worker 1 is assumed to have an exposure frequency of 50 days/year for 5 years; this scenario assumes that Exide retains the property, and represents a worker assigned to several small projects per year over a 5 year period. Construction Worker 2 is assumed to have an exposure frequency of 250 days/year for 1 year; this scenario assumes that Exide sells the property, and the property undergoes one year of redevelopment involving subsurface excavation.

3.1.3 Offsite Natural Gas Facility

At the offsite natural gas facility, an adult commercial worker was evaluated. The worker is assumed to be exposed to surface soil *via* incidental ingestion and dermal contact. The worker is assumed to have an exposure frequency in these areas of 5 days/week for 45 weeks/year, or 225 days/year, and an exposure duration of 25 years.

3.1.4 Arlington Avenue

In the strip along Arlington Avenue outside the eastern border of the facility, an adolescent recreator was evaluated. The recreator is assumed to be exposed to sediment *via* incidental ingestion and dermal contact for 42 days/year. The adolescent recreator is 13-18 years old, therefore his exposure duration is 5 years.

3.1.5 Railroad Ditch

In the Railroad Ditch area along the northern border of the RMC facility, an adolescent recreator was evaluated. The recreator is assumed to be exposed to sediment *via* incidental ingestion and dermal contact for 42 days/year. The adolescent recreator is 13-18 years old, therefore his exposure duration is 5 years.

3.2 Exposure Point Concentrations

In a risk assessment, an Exposure Point Concentration (EPC) represents the concentration of a chemical in an environmental medium to which an individual is exposed. The calculation of EPCs is described below. The EPCs used in this risk evaluation are presented in Table 2. The datasets used and the EPC calculations are presented in Appendix B for lead and Appendix C for arsenic.

Table 2
Exposure Point Concentrations

| | | | | Arsenic 95%UCL | | Lead Mean |
|-------------------------|--|----------------------|---------|-------------------|-----------------------------|--------------|
| Exposure Area | Receptor | Media | Depth | mg/kg | Basis | mg/kg |
| Onsite | Construction Worker 1 & 2, Utility Worker | Soil | 0-5 ft | 123 | NP, Bootstrap | 20,266 |
| | Groundskeeper, Future Site Worker | Soil and Sediment | 0-6 in | (779) | NP, Chebyshev 99% UCL | 20,158 |
| Grassy Area | Construction Worker 1 & 2 | Soil and Sediment | 0-30 in | (818) | NP, Chebyshev 99% UCL | 13,392 |
| | Adolescent Trespasser | Soil | 0-6 in | 60 | NP, Chebyshev 95% UCL | 1,908 |
| | Adolescent Trespasser | Sediment | 0-6 in | 1,387 | Gamma UCL | 89,100 |
| Arlington Ave | Adolescent Recreator | Sediment | 0-3 in | 38 | NP, Chebyshev 95% UCL | 3,032 |
| Railroad Ditch | Adolescent Recreator | Sediment | 0-3 in | 169 | Max | 5,150 |
| Offsite Gas Facility | Worker | Soil | 0-6 in | 28.5 | LN, H-UCL | 1,311 |

NP Nonparametric

LN Lognormal

For arsenic, the EPCs were the 95% upper confidence level on the mean (95UCL) concentration. The 95UCL is used instead of the mean or arithmetic average because it is not possible to know the true mean (USEPA, 1992b). The 95UCL is defined as a value that ..."equals or exceeds the true mean 95% of the time" (USEPA, 1992b). As sampling data become more representative of actual site conditions, uncertainties decrease, and the 95UCL approaches the true mean. The 95UCL values were calculated with ProUCL© according to USEPA guidance (USEPA, 2002a).

To evaluate lead risks, the arithmetic mean soil lead concentration within the exposure area was used as the EPC to be consistent with USEPA guidance (USEPA, 1994; USEPA, 1996)

3.3 Quantification of Exposure

This section discusses the basis for calculating human intake levels resulting from exposures to COPCs other than lead (in this case arsenic), and describes each input parameter. Human intake levels for lead are discussed in Section 5. Exposure estimates represent the daily dose of a chemical taken into the body, averaged over the appropriate exposure period, expressed in the units of milligram (mg) of chemical per kilogram (kg) of human body weight per day. The primary source for the exposure equations used in the HHRA is the USEPA's "Risk Assessment Guidance for Superfund (RAGS)" (USEPA, 1989). The generalized equation for calculating chemical intakes is shown below:

$$I = \frac{EPC \times CR \times EF \times ED}{BW \times AT}$$

where:

I = Intake, the amount of chemical at the exchange boundary (mg/kg body weight-day),

EPC = Exposure Point Concentration, the chemical concentration contacted over the exposure period at the exposure point (e.g., mg/kg in soil),

CR = Contact Rate, the amount of contaminated medium contacted per unit time or event (e.g., soil ingestion rate (mg/day)),

EF = Exposure Frequency, describes how often exposure occurs (days/year),

ED = Exposure Duration, describes how long exposure occurs (yr),

BW = Body Weight, the average body weight over the exposure period (kg), and

AT = Averaging Time, period over which exposure is averaged (days).

Exposure factors (e.g., contact rate, exposure frequency, exposure duration, body weight) describe a receptor's exposure for a given exposure scenario. The values used for each exposure factor are summarized in Table 3 and discussed in detail below. The exposure factor input values are consistent with current USEPA guidance. Where appropriate, exposure parameters were based on site-specific considerations and professional judgment.

¹ Note that this approach is not used to evaluate lead. Consistent with USEPA guidance, lead exposure is evaluated using a child or adult lead model to estimate blood lead levels.

r50505w.doc

3.3.1 Ingestion of Soil

For the soil ingestion pathway intake is calculated as:

$$Intake \left(\frac{mg}{kg \cdot day}\right) = \frac{C_{soil}\left(\frac{mg}{kg}\right) \times B \times IR_{soil}\left(\frac{mg}{day}\right) \times FS \times EF\left(\frac{days}{yr}\right) \times ED(yrs) \times 10^{-6} \frac{kg}{mg}}{BW(kg) \times AT(days)}$$

where:

 C_{soil} = Concentration of the chemical in soil (mg/kg)

B = Relative Bioavailability, the relative oral absorption fraction (unitless)

 IR_{soil} = Soil Ingestion Rate (mg/day)

FS = Fraction of Soil from the site (unitless)

EF = Exposure Frequency (days/year)

ED = Exposure Duration (years)

BW = Body Weight (kg)

AT = Averaging Time (days)

Gradient used conservative USEPA-recommended values for each of the input parameters. The basis for each value used is detailed below.

Soil Concentrations (C_{soil}). As summarized in Section 3.2, the 95UCL was used as the EPC.

Relative Bioavailability (B). To accurately quantify potential exposures from ingestion of soil, it is important to consider the amount of a chemical that is solubilized in gastrointestinal fluids and absorbed across the gastrointestinal tract into the bloodstream. A chemical present in soil may be absorbed less completely than the same dose of the chemical administered in toxicity studies used to evaluate safe dose levels. A relative bioavailability estimate for a specific compound represents the absorption fraction from soil (the exposure route of concern) relative to the absorption fraction from food or water (in most toxicity studies, chemical doses are administered in food or water).

It is widely recognized that bioavailability of many metals and organics from soil tends to be considerably lower than bioavailability from food or water. USEPA guidance recognizes the need to make adjustments for the reduced bioavailability of compounds in soil. Specifically, in Appendix A of USEPA's Risk Assessment Guidance for Superfund (USEPA, 1989, pg. A-3), USEPA notes:

If the medium of exposure in the site exposure assessment differs from the medium of exposure assumed by the toxicity value (e.g., RfD values usually are based on or have been adjusted to reflect exposure via drinking water, while the site medium of concern may be soil), an absorption adjustment may, on occasion, be appropriate. For example, a substance might be more completely absorbed following exposure to contaminated drinking water than following exposure to contaminated food or soil (e.g., if the substance does not desorb from soil in the gastrointestinal tract).

USEPA Region 10 risk assessment guidance provides default values for the bioavailability of arsenic in soil. Region 10 notes that if the site is a smelter site and its appears likely that the arsenic exists primarily as finely-grained oxides from smelter stack emissions, then a value of 80% relative bioavailability may be assumed. Region 10 notes that this value is supported by a conservative interpretation of the scientific literature (USEPA Region 10, 1997). A relative bioavailability of 80% was used for arsenic in this risk assessment.

For lead, the USEPA recommends an oral absorption factor for adults of 0.12 for ingestion of lead in soil, based on 20% absorption of soluble lead, and a relative bioavailability of 60% for lead in soil (i.e., $0.12 = 0.2 \times 0.6$) (USEPA, 1996). Gradient used the recommended USEPA absorption factor of 0.12 to evaluate ingestion of lead contaminated soil for adult receptors.

Soil Ingestion Rate (IR_{soil}). A daily soil and dust ingestion rate of 50 mg/day was used for the adolescent trespasser, adolescent recreator, site worker, and offsite gas facility worker. USEPA considers this value to be a reasonable central estimate of adult soil ingestion and notes that although this value is highly uncertain, "a recommendation for an upper percentile value would be inappropriate" (USEPA, 1997a). A daily soil and dust ingestion rate of 100 mg/day was used for the groundskeeper (USEPA, 2002b). A daily soil and dust ingestion rate of 330 mg/day was used for the onsite construction worker and the onsite utility worker, as these receptors are assumed to have more intensive contact with soil than the other adult receptors (USEPA, 2002b).

Fraction of Soil From the Site (FS). For all receptors, it was assumed that 100% of the individual's daily soil exposure occurred at the site. This assumption is likely to overestimate exposure to contaminated soil for workers, trespassers, and recreators because workers are assumed to be at the site for only 8 hours per day, and trespassers are likely present less than 2 hours per visit.

Exposure Frequency (EF) and Exposure Duration (ED). The exposure frequency and duration used for each receptor are discussed in Section 3.1.1 to 3.1.3. For the site worker, groundskeeper, and offsite gas worker, the exposure duration is 25 years. This is the 95th percentile duration that an individual stays at any one workplace (USEPA, 1991). Hence, this assumption overestimates exposures for most workers, because the median occupational tenure of the working population has been estimated to be 6.6 years (USEPA, 1997a).

Body Weight (BW). Although the average U.S. adult body weight in the current Exposure Factors Handbook (USEPA, 1997a) is 71.8 kg, a mean adult body weight of 70 kg (USEPA, 1991) was used in the HHRA, so that the body weight would be consistent with that used in deriving the toxicity factors. Average body weight for the adolescent trespasser and recreator (13-18 year old) was calculated from data in USEPA's Exposure Factors Handbook and used in the HHRA (USEPA, 1997a).

Averaging Time (AT). For non-cancer risks, the averaging time was equal to the exposure duration multiplied by 365 days/year. For cancer risks, exposures were averaged over a 70-year average lifetime (USEPA, 1991). Although the current life expectancy for men and women in the U.S. is 76.7 years (USEPA, 1997a), a value of 70 years (25,550 days) was used to be consistent with the value used in deriving the toxicity factors.

3.3.2 Dermal Contact with Surface Soil

For dermal exposure to contaminants in soil, a dermal intake (the amount absorbed into the body) is calculated as (USEPA, 2004c):

$$Intake \left(\frac{mg}{kg \cdot day}\right) = \frac{C_{soil}\left(\frac{mg}{kg}\right) \times DA \times AF\left(\frac{mg}{cm^{2}}\right) \times SA\left(\frac{cm^{2}}{event}\right) \times EF\left(\frac{events}{yr}\right) \times ED(yrs) \times 10^{-6} \frac{kg}{mg}}{BW(kg) \times AT(days)}$$

13

where:

 C_{soil} = Concentration of the chemical in soil (mg/kg),

DA = Dermal Absorption factor (unitless)
AF = Soil/skin Adherence Factor (mg/cm²),

SA = Skin surface Area exposed (cm²/exposure event),

EF = Exposure Frequency (exposure events/year),

ED = Exposure Duration (years), BW = Body Weight (kg), and AT = Averaging Time (days).

There are three parameters in this equation that are different from those discussed in the previous section (Section 3.3.1). Only those parameters unique to the dermal exposure equation, dermal absorption fraction (DA), the soil adherence factor (AF), and the skin surface area (SA), are discussed in this section.

Note that since absorbed doses are used for the dermal pathway, the toxicity criteria are adjusted so they apply to absorbed doses. This adjustment is discussed in more detail in the toxicity section (Section 4).

Dermal Absorption Fraction (DA). The dermal absorption fraction represents the amount of a chemical in contact with skin that is absorbed through the skin and into the bloodstream. The dermal absorption fraction for arsenic (0.03) was obtained from USEPA's dermal risk assessment guidance (USEPA, 2004c; Table 3.4).

Soil to Skin Adherence Factor (AF). The adherence factor relates the amount of soil that adheres to the skin per unit of surface area (USEPA, 2004c). Adherence factors vary depending on the properties of the soil, the part of the body, and the type of activity. Gradient used the 50th percentile weighted adherence factors from USEPA's dermal risk assessment guidance (USEPA, 2004c). The AF for utility workers (0.2 mg/cm²) was used for the construction worker, utility worker, groundskeeper, and offsite gas facility worker. EPA's recommended AF for the residential adult (0.07 mg/cm²) was used for the future site worker, adolescent trespasser, and adolescent recreator.

Skin Surface Area Exposed (SA). This parameter reflects the amount of skin that is available for exposure to soil. The skin surface areas used in the HHRA were 3300 cm² for the construction worker, utility worker, site worker, groundskeeper, and offsite gas facility worker, based on the face, hands, and

forearms; and 4270 cm² for the trespasser and recreator, based on the face, hands, forearms, and lower legs. Surface areas were calculated using USEPA's Exposure Factors Handbook (USEPA, 1997a).

4 Toxicity Assessment

4.1 Overview of Toxicity Values

Gradient has evaluated potential cancer and non-cancer risks from exposure to arsenic using dose-response relationships for carcinogenicity (oral Cancer Slope Factors) and systemic toxicity (oral Reference Doses). Lead toxicity is discussed separately in Section 4.2. The primary source of toxicity values was the USEPA's Integrated Risk Information System (IRIS) (USEPA, 2004a). Toxicity values in IRIS undergo a rigorous peer review process and are generally considered to be of high quality. The toxicity factors used in the HHRA are summarized in Table 4.

Table 4
Toxicity Factors

| Compound | RfD _{oral} (mg/kg- day) | Critical Effect | RfD Source | Uncertainty Factor | Oral Absorption | RfD _{dermal} (mg/kg- day) | CSF _{oral} (mg/kg- day) | CSF _{dermal} (mg/kg- day) |
|----------|--|---|---------------|-----------------------|--------------------|--|--|--|
| Arsenic | 0.0003 | Hyperpigmentation, keratosis and possible vascular complications | IRIS | 3 | 95% | 0.0003 | 1.5 | 1.5 |

4.1.1 Oral Reference Doses (RfD_{oral})

An RfD is an estimate of daily exposure that a sensitive population can experience over a lifetime with a negligible risk of systemic health effects. The USEPA derives RfDs by first identifying the highest dose level that does not cause observable adverse effects (*i.e.*, the No Observed-Adverse Effect Level, or NOAEL; USEPA, 1993). If a NOAEL was not identified, a Lowest Observed Adverse Effect-Level, or LOAEL, may be used. This dose level is then divided by uncertainty factors to calculate an RfD. An uncertainty factor of 100 is often used, to account for interspecies differences (if animal studies were used) and sensitive human subpopulations (*e.g.*, children and the elderly; USEPA, 1993). Additional uncertainty factors may be used, depending on the quality of the toxicological data.

4.1.2 Oral Cancer Slope Factors (CSF_{oral})

The CSF is an upper bound estimate of carcinogenic potency used to calculate risk from exposure to carcinogens, by relating estimates of lifetime average chemical intake to the incremental risk of an individual developing cancer over their lifetime (USEPA, 1992c). The CSFs recommended by the

USEPA are conservative upper bound estimates, which means that the USEPA is reasonably confident that the "true" cancer risk does not exceed the estimated risk calculated using the CSF, and may be as low as zero.

4.1.3 Dermal Reference Doses (RfD_{dermal})

There are no USEPA-derived toxicity values based specifically on toxicity studies involving dermal exposures. In the absence of dermal-specific RfDs, oral toxicity factors are used, assuming that once a chemical is absorbed into the blood stream, the health effects are similar regardless of whether the route of exposure is oral or dermal. However, since oral toxicity criteria are based on the amount of a chemical *administered* per unit time and body weight (chemical intake), they need to be adjusted to be applicable to *absorbed* doses (dermal exposures are expressed as absorbed intake levels) (USEPA, 1989; 1992a; 2004c).

Since most RfDs are based on studies where a chemical is administered in food or water, this adjustment is made using the oral absorption efficiency for that chemical. If oral absorption is very high (almost 100%), then the absorbed dose is virtually the same as the administered dose, and no adjustment of the toxicity factor is necessary. If oral absorption is very low (e.g., 5%), the absorbed dose is much smaller than the administered dose, and an adjustment of the toxicity criteria is necessary. For any given chemical, the USEPA recommends adjusting the oral toxicity factor for use in evaluating dermal risks only when the oral absorption for that chemical is less than 50%, to "obviate the need to make comparatively small adjustments in the toxicity value that would otherwise impart on the process a level of accuracy that is not supported by the scientific literature" (USEPA, 2004c).

For non-cancer effects, this adjustment is made by multiplying the oral RfD (for applied doses) by the oral absorption efficiency (i.e., $RfD_{oral} \times Abs_{oral} = RfD_{dermal}$). For arsenic, the oral absorption efficiency is 95%, therefore no adjustment is necessary and the RfD_{dermal} is the same as the RfD_{oral} (Table 4).

4.1.4 Dermal Cancer Slope Factors (CSF_{dermal})

There are no USEPA-derived toxicity values specifically for cancer studies involving dermal exposures. In the absence of dermal-specific CSFs, oral CSFs are used, assuming that once a chemical is absorbed into the blood stream, the carcinogenic effect is similar regardless of whether the route of

exposure is oral or dermal. However, since oral CSFs are based on the amount of a chemical administered per unit time and body weight (chemical intake), they need to be adjusted to be applicable to absorbed doses (dermal exposures are expressed as absorbed intake levels) (USEPA, 1989; 1992a; 2004c). For any given chemical, the USEPA recommends adjusting the oral CSF for use in evaluating dermal risks only when the oral absorption for that chemical is less than 50%, to "obviate the need to make comparatively small adjustments in the toxicity value that would otherwise impart on the process a level of accuracy that is not supported by the scientific literature" (USEPA, 2004c).

For cancer, this adjustment is made by dividing the oral CSF (for applied doses) by the oral absorption efficiency (i.e., CSF_{oral} / $Abs_{oral} = CSF_{dermal}$), if the oral absorption efficiency is less than 50%. For arsenic, this value is 95%, therefore the CSF_{dermal} is the same as the CSF_{oral} (Table 4).

4.2 Toxicity Values for COPCs

The basis of the arsenic toxicity values is described in this section and summarized in Table 4. Lead toxicity is also discussed in this section because of the unique way exposure and risk are evaluated for this metal.

4.2.1 Arsenic

The toxicity criteria for arsenic were obtained from the USEPA IRIS database (USEPA, 2004a). The derivation of each of these values, and the scientific uncertainties concerning arsenic toxicity, are discussed below.

4.2.1.1 Arsenic RfD_{oral}

USEPA cites an RfD_{oral} for arsenic of 0.0003 mg/kg-day (USEPA, 2004a). The arsenic RfD_{oral} is based on increased incidence of hyperpigmentation, keratosis and possible vascular complications in a study of a large population (over 40,000 people) in Taiwan with chronic exposure to arsenic in drinking water and food (Tseng, 1977; Tseng *et al.*, 1968). The USEPA characterized a NOAEL of 0.0008 mg/kg/day for skin lesions in the Tseng study, based on the drinking water concentration in the NOAEL group (0.009 mg/L), an assumed drinking water ingestion rate of 4.5 L, daily arsenic intake from sweet potatoes and rice of 0.002 mg/day, and an average Taiwanese body weight of 55 kg ((0.009 mg/L × 4.5 L/day) + 0.002 mg/day / 55 kg) (Abernathy *et al.*, 1989). An uncertainty factor of 3 (based on the lack of

reproductive toxicity data and uncertainty regarding toxicity in sensitive individuals) was applied to the NOAEL to derive an RfD of 0.0003 mg/kg/day (0.0008/3). Overall, the USEPA has "medium" confidence in the study, "medium" confidence in the database (due to poor characterization of the dose levels in the Tseng and other supporting studies), and "medium" confidence in the RfD_{oral} for arsenic. It is noted in the arsenic IRIS file that a clear consensus does not exist among USEPA scientists regarding arsenic systemic toxicity (USEPA, 2004a).

4.2.1.2 Arsenic CSF_{oral}

USEPA concluded that arsenic is a "human carcinogen," a weight-of-evidence classification for carcinogenicity of "A" (USEPA, 2004a). This classification is based on sufficient evidence of carcinogenicity in human populations. Lung cancer has been associated with inhalation of arsenic, and skin, bladder, and possibly other internal cancers have been associated with ingestion of arsenic in drinking water.

In IRIS, the USEPA recommends a CSF_{oral} value for arsenic of 1.5 (mg/kg/day)⁻¹ (USEPA, 2004a). This value is based on skin cancer incidence rates in the same Taiwanese study used as the basis for the RfD_{oral} value (Tseng, 1977; Tseng *et al.*, 1968). This value was calculated using a multistage model, assuming a drinking water ingestion rate of 3.5 L/day for Taiwanese males and 2 L/day for Taiwanese females, an average Taiwanese body weight of 55 kg, and an average U.S. body weight of 70 kg.

There is currently considerable debate among the scientific community regarding the arsenic CSF_{oral}. Many researchers believe that the current value of 1.5 (mg/kg/day)⁻¹ may overestimate cancer risks for U.S. populations (see, for example, Slayton *et al.*, 1996; Chappell *et al.*, 1997).

4.2.1.3 Arsenic RfD_{derm} and CSF_{derm}

In general, for dermal exposures (expressed as absorbed intake levels), the RfD_{oral} and CSF_{oral} are adjusted to be applicable to absorbed doses (USEPA, 1989; 1992a). This adjustment is made assuming that once a chemical is absorbed into the blood stream, the health effects are similar regardless of whether the route of exposure is oral or dermal. However, since oral absorption for arsenic is about 95% (USEPA, 2004c), and the USEPA recommends adjusting dermal toxicity factors only when oral absorption is less than 50%, no adjustment was made for arsenic.

4.2.2 Lead

The ingestion of lead at certain levels can result in significant health effects, particularly among children. Epidemiological investigators have reported a correlation between blood lead levels (BLLs) in children and adverse health effects. High levels of lead intake can cause kidney damage, convulsions, coma, and even death (ATSDR, 1999). However, health effects resulting from lower levels of lead exposure are more common, and are related to cognitive and neuro-behavior impacts, including the impairment of intellectual performance.

The USEPA has not established any toxicity criteria (RfD, CSF) for lead (USEPA, 2004b); instead, lead risks are evaluated by modeling blood lead levels. Lead risks in adults were evaluated using USEPA's Adult Lead Model (USEPA, 2003). This model is discussed in more detail in Section 5.4.

The USEPA has assigned lead a Weight-of-Evidence Classification for human carcinogenicity of "B2", a "probable human carcinogen," based on sufficient animal evidence but inadequate human evidence (USEPA, 2004b). Even though the weight of evidence for lead carcinogenicity is B2, the USEPA does not evaluate lead cancer risk using a CSF, having concluded that neurological effects in young children are the most relevant endpoint.

5 Risk Characterization

In this section, cancer and non-cancer health risks are estimated by combining the information from Sections 2 through 4. The calculations used to estimate cancer and noncancer risks are presented in Sections 5.1 and 5.2, respectively. Section 5.3 discusses the calculated cancer and noncancer risks for each exposure area. Section 5.4 presents the lead risks by exposure area. Section 5.5 provides a qualitative discussion of the most significant sources of uncertainty in the risk estimates.

5.1 Calculation of Cancer Risks

Excess lifetime cancer risks are characterized as the incremental probability that an individual will develop cancer during his or her lifetime due to chemical exposure to constituents at the site under the specific exposure scenarios evaluated. The term "incremental" implies the risk above the background cancer risk experienced by all individuals in the course of daily life. According to Greenlee *et al.* (2001), the lifetime probability of developing cancer (*i.e.*, background cancer risk) is approximately 0.435 in men, and 0.383 in women. Cancer risks are expressed as a unitless probability (*e.g.*, one in a million, or 10^{-6}) of an individual developing cancer over a lifetime, above background risk, as a result of exposure to impacted environmental media at a site.

Excess (incremental) cancer risks for all of the exposure pathways (oral, dermal, and inhalation) are calculated using intake estimates (lifetime average daily doses, calculated in Section 3 as part of the exposure assessment) and CSFs (summarized as part of the toxicity assessment in Section 4) as follows (USEPA, 1989):

$$CancerRisk = Intake \left(\frac{mg}{kg \cdot day}\right) \times CSF \left(\frac{mg}{kg \cdot day}\right)^{-1}$$

For ingestion pathways, oral intake estimates (expressed as applied or administered dose levels) are multiplied by the oral CSF (applicable to applied/administered doses). Similarly, for inhalation pathways, inhalation intake estimates (also expressed as applied or administered dose levels) are multiplied by the inhalation CSF (applicable to applied/administered doses). For dermal exposures, dermal intake estimates (expressed as an absorbed dose level) are multiplied by an adjusted oral CSF (adjusted to apply to absorbed doses) (USEPA, 2004c). The total cancer risk for each receptor is the sum of the risks across all of the exposure pathways.

5.2 Calculation of Noncancer Risks

Risks from non-carcinogenic health effects are expressed as hazard quotients rather than as probabilities. A hazard quotient compares the calculated exposure (average daily doses, calculated as part of the exposure assessment in Section 3) to acceptable reference exposures derived by the USEPA (e.g., RfDs, summarized as part of the toxicity assessment in Section 4). The hazard quotient is calculated from the RfD as follows (USEPA, 1989):

$$HazardQuotient = \frac{Intake \left(\frac{mg}{kg \cdot day}\right)}{RfD \left(\frac{mg}{kg \cdot day}\right)}$$

For the ingestion exposure route an oral intake estimate (expressed as applied or administered dose) is divided by the oral RfD (applicable to applied/administered dose). Similarly, for the inhalation exposure route an inhalation intake estimate (also expressed as applied or administered dose) is divided by the inhalation RfD (applicable to applied/administered dose). For dermal exposure, a dermal intake estimate (expressed as an absorbed dose) is divided by an adjusted oral RfD (adjusted to apply to absorbed dose).

Hazard indices are calculated for each receptor and exposure pathway, according to USEPA guidance (1989). A hazard index greater than 1.0 is considered to represent a significant health risk. Because a hazard quotient is simply a ratio of site exposures to reference exposure levels (e.g., RfDs, RfCs, etc.), hazard indices do not represent the probability that an adverse health effect could occur. They simply indicate whether an estimated exposure for an individual presents a significant noncancer health risk, based on the USEPA's recommended reference dose.

5.3 Estimated Cancer and Noncancer Risks

The estimated cancer and noncancer risks for arsenic are discussed below by exposure area. Lead risks are discussed separately in Section 5.4. Cancer risks are summarized in Table 5. The total cancer risk for each receptor is the sum of the risks over all exposure routes and all exposure periods. Noncancer risks are also summarized in Table 5. The total noncancer risk for each receptor is the sum of

22

the risks over all exposure routes. The detailed risk calculation tables in Appendix A present the arsenic risks calculated for each receptor and exposure pathway. The percent contribution of each exposure pathway to the total risk is also shown.

5.3.1 Main Facility Area

In the main facility area onsite, we evaluated two types of construction workers (Construction Workers 1 & 2) and a utility worker for exposure to arsenic in subsurface soil *via* incidental ingestion and dermal contact.

The total excess lifetime cancer risk is 7×10^{-6} for both construction workers, and 3×10^{-6} for the utility worker. These risk estimates are within USEPA's target risk range of 1×10^{-6} to 1×10^{-4} .

The total hazard index (HI) is 0.2 for Construction Worker 1, 1 for Construction Worker 2, and 0.05 for the utility worker. The remaining values are well below a HI of 1.0.

5.3.2 Grassy Area

In the grassy area located north, south, and east of the main facility, we evaluated a groundskeeper, a future site worker, two types of construction workers (Construction Workers 1 & 2), an adolescent trespasser exposed to soil, and an adolescent trespasser exposed to sediment. These receptors were assumed to be exposed to arsenic in soil or sediment *via* incidental ingestion and dermal contact.

The total excess lifetime cancer risks are 8×10^{-5} for the groundskeeper, 1×10^{-4} for the future site worker, 5×10^{-5} for both construction workers, 3×10^{-7} for the adolescent trespasser exposed to soil, and 7×10^{-6} for the adolescent trespasser exposed to sediment. These risk estimates are within or less than USEPA's target risk range of 1×10^{-6} to 1×10^{-4} .

The total hazard index (HI) is 0.5 for the groundskeeper, 0.7 for the future site worker, 2 for Construction Worker 1, 8 for Construction Worker 2, 0.01 for the adolescent trespasser exposed to soil, and 0.2 for the adolescent trespasser exposed to sediment. The two construction workers exceed a HI of 1.0. The other four receptors are below a HI of 1.0.

r50505w.doc

5.3.3 Arlington Avenue

In the Arlington Avenue area along the eastern border of the RMC property, we evaluated an adolescent recreator exposed to arsenic in surface sediment *via* incidental ingestion and dermal contact.

The total excess lifetime cancer risk for exposure to arsenic in sediment is 4×10^{-7} for the Arlington Avenue recreator. This risk estimate is below USEPA's target risk range of 1×10^{-6} to 1×10^{-4} .

The total hazard index (HI) for exposure to arsenic in sediment is 0.01 for the Arlington Avenue recreator. This value is well below a HI of 1.0.

5.3.4 Railroad Ditch

In the Railroad Ditch area along the northern border of RMC property, we evaluated an adolescent recreator exposed to arsenic in surface sediment *via* incidental ingestion and dermal contact.

The total excess lifetime cancer risk for exposure to arsenic in sediment is 2×10^{-6} for the Railroad Ditch recreator. This risk estimate is within USEPA's target risk range of 1×10^{-6} to 1×10^{-4} .

The total hazard index (HI) for exposure to arsenic in sediment is 0.05 for the Railroad Ditch recreator. This value is well below a HI of 1.0.

5.3.5 Offsite Natural Gas Facility

At the offsite natural gas facility to the west of the RMC property, we evaluated a facility worker exposed to arsenic in surface soil *via* ingestion and dermal contact.

The total excess lifetime cancer risk is 8×10^{-6} for the gas facility worker. This risk estimate is within USEPA's target risk range of 1×10^{-6} to 1×10^{-4} .

The total hazard index (HI) is 0.05 for the offsite gas facility worker. This value is well below a HI of 1.0.

Table 5
Summary of Cancer and Noncancer Risks

| Off Site Natural Gas Facility | Soil | Adult Worker | 8E-06 | 0.05 |

5.4 Lead Risk Assessment

5.4.1 Adult Lead Model

Blood lead levels (BLLs) in adolescents and adults are assessed using USEPA's Adult Lead Model (ALM) (USEPA, 1996). USEPA's Adult Blood Lead Model predicts a median BLL estimate for an adult as a function of the baseline BLL plus an increment that is attributable to exposure to site soil. This increment is a function of the biokinetic slope factor, the concentration of lead in soil, the soil ingestion rate, the fraction of lead in soil that is absorbed, and the exposure frequency. EPA has selected a target BLL for an adult female, in order to protect a developing fetus such that no more than 5% of fetuses would be expected to have BLLs exceeding $10 \mu g/dL$.

The basic form of the equation for the ALM is as follows:

$$BLL_{adult} = PbB + \frac{(EF \times AF \times PbS \times IR \times BKSF)}{AT}$$

The input values used in the model are summarized in Table 6 and described below. First, an average baseline lead concentration in blood (PbB_{base}) for adults is identified to account for continuing exposure to background levels of lead in food, soil, and dust, and pre-existing body burdens due to prior

25

lead exposures. Baseline BLLs were obtained from the most recent National Health and Nutrition Examination Survey, from 1999-2000 (NHANES, 2000) (U.S. Public Health Service, 2004) (see Appendix E). For adults we used the geometric mean (GM) and geometric standard deviation (GSD) BLLs for women of childbearing age (age 20-49). For the adolescent trespasser, we used the GM and GSD BLLs for males and females combined, for 13-18 year olds. To this baseline, the model adds the incremental increase in blood lead due to the lead source of interest (in this case, exposure to lead *via* ingestion of soil).

The concentration of lead in soil (PbS) is the mean lead concentration in each exposure area. Lead uptake is calculated by multiplying the concentration of lead in soil by the soil ingestion rate (IR) and the absorption fraction (AF) for lead in soil. The AF is the amount of lead that is absorbed into the bloodstream from the gastrointestinal tract. The exposure frequency (EF) varies by receptor and exposure area. The EFs used for each receptor are presented in Table 3. The averaging time (AT) for chronic exposure to lead in soil is assumed to be one year (i.e., 365 days). The biokinetic slope factor (BKSF) relates the incremental lead uptake into the body to an incremental increase in blood lead level in adults. USEPA's default value of 0.4 was used for the BKSF.

Table 6
Adult Lead Model Input Values

| Term | Definition | Value |
|------------------|--|--------------------------------|
| PbB ₀ | Geomean baseline BLL (µg/dL) for Adult females | |
| | (age 20-49 yr) from NHANES 2000 | 1.2 |
| GSD | Geometric standard deviation for Adult females | 1.8 |
| PbB_0 | Geomean baseline BLL (μ g/dL) for 13-18 yr old males and females | 1.1 |
| GSD | Geometric standard deviation for 13-18 yr old males and females | 1.8 |
| EF | Exposure Frequency (i.e., number of days during the averaging time an individual is exposed to the lead source being evaluated (days)) | Receptor-specific |
| AT | Averaging Time (days) | 365 |
| PbS | Soil lead concentration (µg/g) | Area-Specific |
| IR | Soil Ingestion Rate (g/day) | Receptor-specific 0.05 or 0.10 |
| AF | Fraction of ingested lead absorbed into the blood stream (dimensionless) | 0.12 |
| BKSF | Biokinetic Slope Factor (change in blood lead per μ g change in daily lead uptake) (μ g/dL per μ g/day) | 0.4 |

Total BLLs for adults are predicted by adding the estimated incremental increase in blood lead to the average baseline BLL. A geometric standard deviation (GSD) appropriate for adults is used to estimate the probable range of BLLs around the predicted geometric mean adult BLL from the model. For this evaluation, we used the actual GSDs for the BLLs obtained from the NHANES-2000 database.

BLLs estimated using the ALM are evaluated based on a comparison to the USEPA risk management criterion for lead. Specifically, the health protection goal of the USEPA Office of Solid Waste and Emergency Response is to "limit exposure to soil lead levels such that a typical (or hypothetical) child or group of similarly exposed children would have an estimated risk of no more than 5% of exceeding a blood lead of 10 μ g/dL" (USEPA, 1998). The Centers for Disease Control (CDC) recommend that "the goal of all lead poisoning prevention activities should be to reduce children's BLLs below 10 μ g/dL" (CDC, 1991). Based on a goal of keeping the BLL in children at or below 10 μ g/dL, the BLL for women of child-bearing age should not exceed 11.1 μ g/dL, because the fetal BLL is approximately 90% of the maternal BLL (*i.e.*, 90% of 11.1 μ g/dL is 10 μ g/dL). A BLL goal of 10 μ g/dL was used for the adolescent trespasser.

27

The adult lead modeling results for all receptors, along with the input values, the predicted BLLs, and the probability of exceeding the target BLL, are presented in Table 7. The adult lead modeling results are discussed below by exposure area. The dermal exposure route for lead in soil was not evaluated because this exposure route is typically insignificant when compared to ingestion. The ALM makes no provision for assessing dermal exposures.

Footnotes: Construction Worker 1 is as described in the risk assessment work plan, i.e., short-term projects spread out over a 5 year period. Construction Worker 2 presupposes redevelopment of the property including a year-long excavation/construction scenario for new buildings. Source: U.S. EPA (1996). Recommendations of the Technical Review Workgroup for Lead

for an Interim Approach to Assessing Risks Associated with Adult Exposures to Lead in Soil

5.4.2 Main Facility Area

In the main facility area, lead risks were evaluated for two types of construction workers and a utility worker exposed to subsurface soil (0-5 ft). The predicted 95th percentile fetal BLLs are 34 μ g/dL for Construction Worker 1, 161 μ g/dL for Construction Worker 2, and 9.1 μ g/dL for the utility worker. The predicted BLL for the fetus of both construction workers exceeds the BLL goal of 10 μ g/dL, thus lead in subsurface soil poses an unacceptable risk in the main facility area. The exceedance is due to the elevated subsurface soil EPC of 20,266 mg/kg, which represents the average concentration for depths of 0-5 ft across the site. The utility worker has a much lower exposure frequency than the construction worker, thus his predicted 95th percentile BLL is below the adult 95th percentile goal of 10 μ g/dL.

5.4.3 Grassy Area

In the grassy area, lead risks were evaluated for a future site worker, a groundskeeper, two types of construction workers, an adolescent trespasser exposed to surface soil, and an adolescent trespasser exposed to sediment. The predicted 95th percentile fetal BLLs are 19 μ g/dL for the groundskeeper, 48 μ g/dL for the future site worker, 24 μ g/dL for Construction Worker 1, 107 μ g/dL for Construction Worker 2, 4 μ g/dL for the trespasser exposed to soil, and 66 μ g/dL for the trespasser exposed to sediment. The predicted fetal BLLs for all receptors except for the trespasser exposed to lead in soil exceed the BLL goal of 10 μ g/dL, thus lead in soil and sediment poses an unacceptable risk in this exposure area.

5.4.4 Arlington Avenue

In the Arlington Avenue area, lead risks were evaluated for an adolescent recreator exposed to surface sediment. The predicted 95th percentile fetal BLL is 6.9 μ g/dL for this adolescent recreator. The predicted BLL is below the goal of 10 μ g/dL, therefore, lead does not pose a significant risk to a recreator exposed to surface sediment in this exposure area.

5.4.5 Railroad Ditch

In the Railroad Ditch area, lead risks were evaluated for an adolescent recreator exposed to surface sediment. The predicted 95th percentile fetal BLL is 9.9 µg/dL for this adolescent recreator. The

31

predicted BLL is below the goal of 10 μ g/dL, therefore, lead does not pose a significant risk to a recreator exposed to surface sediment in this exposure area.

5.4.6 Offsite Natural Gas Facility

At the offsite natural gas facility, lead risks were evaluated for an offsite worker exposed to surface soil. The predicted 95th percentile fetal BLL is 7.4 μ g/dL for the offsite worker. The predicted BLL is below the goal of 10 μ g/dL, therefore, lead does not pose a significant risk to a worker exposed to surface soil in this exposure area.

5.5 Uncertainty Analysis

The process of evaluating human health risks involves multiple steps. Inherent in each step of the process are uncertainties that ultimately affect the final risk estimates. Uncertainties may exist in numerous areas, including sample collection, laboratory analysis, derivation of toxicity values, and estimation of potential site exposures. These uncertainties may result in either an over- or underestimation of risks. However, for this risk assessment, where uncertainties existed, Gradient took a conservative approach in regards to parameters, assumptions, and methodologies, so as to overestimate potential exposures and risks. The most important contributors to uncertainty in this risk assessment are discussed below.

5.5.1 Uncertainties in Exposure Assessment

Soil Ingestion Rate. Lead risks were evaluated for onsite workers and grassy area construction workers using a soil ingestion rate of 0.10 g/day while all other receptors were evaluated using the 0.05 g/day default. The lead risks use an average soil ingestion rate, because average inputs are required by the ALM. Arsenic risks were evaluated using 0.330 g/day for the onsite and construction workers, 0.100 g/day for the groundskeeper, and 0.050 g/day for all other receptors. The arsenic risks use a highend ingestion rate that represents the "reasonable maximum exposure" or RME. However, a survey of recent literature suggests that the average soil ingestion rate value for adults is closer to 0.02 g/day (Bowers et al., 1994). Therefore, the soil ingestion rates used here are conservative in that they will tend to overestimate risk.

Lead Absorption Fraction. A lead absorption fraction used in the ALM was USEPA's default value of 0.12. This value is based on 20% absorption of lead from water, and 60% relative bioavailability of lead from soil $(0.20 \times 0.60 = 0.12)$. The 20% absorption of lead from water is an upper-end value based on consumption on an empty stomach. This is a conservative assumption that may overestimate risk. O'Flaherty (1993) suggests that a value of 8% may be a more appropriate absorption value for food and water in adults. This value assumes that people consume food at average mealtimes throughout the day, therefore the lead absorption rate is slower due to the presence of food in the stomach. If we use an adult soil ingestion rate of 0.02 g/day, combined with a lead absorption fraction of 8% (or for soil, $0.08 \times 0.6 = 0.048$), we find that the lead risks calculated for adult receptors could be on the order of 60-70% lower than those presented here. Thus the adult lead risks presented in this report are likely conservative overestimates.

Fraction from site. Each receptor's daily soil exposure was assumed to be solely from impacted soil within the exposure area. This is a conservative assumption, since it is expected that workers would be at the site for only 8 hours a day, and would be exposed to soil and dust from other sources during the remaining part of each day (e.g., from home). For instance, in the grassy area, the exposure is likely overestimated for the future site worker, since we assumed he would obtain 100% of this daily soil ingestion during the hour or so that he visits the grassy area at lunchtime.

Exposure Duration. Gradient assumed an upper bound (95th percentile) exposure duration of 25 years for the future site worker, groundskeeper, and offsite gas facility worker (USEPA, 1991). This assumption is conservative and is likely to result in an overestimate of exposure and risk for most workers, since many workers do not remain at the same job for 25 years.

5.5.2 Uncertainties in Arsenic Risk Assessment

Risk management decisions for arsenic are confounded by the unusual nature of natural arsenic background risks, which for both food and water yield cancer risks of 10⁻⁴ or higher, and because of the substantial uncertainty associated with the arsenic cancer slope factor. This section describes some of the unique uncertainties associated with arsenic. In general, the assumptions we have used tend to overestimate arsenic risks.

5.5.2.1 Background Levels of Arsenic in Food, Water, Air, and Soil

Humans are exposed to low levels of arsenic in food, water, air, and soil (ATSDR, 2000). Food is typically the largest source of arsenic exposure, with dietary exposure accounting for about 70% of the daily intake of inorganic arsenic (Borum and Abernathy, 1994). The U.S. EPA estimates that the U.S. population ingests approximately 18 μ g of inorganic arsenic every day from food (USEPA 1988). This translates into a 4×10^{-4} cancer risk estimate based on continuous lifetime exposure, and EPA's current assessment of the carcinogenic potential of arsenic.

In the U.S., the average background level of arsenic in drinking water is approximately 2 μg/L (ATSDR, 2000). The recent U.S. EPA rule allows a permissible level or maximum contaminant level (MCL) of 10 μg/L arsenic in drinking water (USEPA, 2001a), a 5-fold lower value than the prior MCL of 50 μg/L. The rule allows community and non-transient, non-community water systems 5 years to attain compliance with the new MCL. Assuming the average background level and an ingestion rate of 2 L drinking water per day, an adult would ingest 4 μg inorganic arsenic per day. At the new MCL of 10 μg/L, an adult would ingest 20 μg inorganic arsenic per day, while at the old MCL of 50 μg/L, an adult would ingest 100 μg inorganic arsenic per day. These values translate into a range of cancer risk estimates between 9×10⁻⁵ and 2×10⁻³ based on continuous lifetime exposure, and EPA's current assessment of the carcinogenic potential of arsenic. EPA currently estimates that approximately 11 million people in the U.S. are served by community water systems with arsenic levels above the revised MCL. These people therefore have a cancer risk from water alone above 4×10⁻⁴.

The mean levels of arsenic in ambient air range from less than 1 to 3 ng/m³ in rural areas and from 20 to 30 ng/m³ in urban areas (ATSDR, 2000). Assuming an inhalation rate of 20 m³/day, an adult would breathe in less than 0.02 to 0.06 μ g inorganic arsenic per day in rural areas, and 0.4 to 0.6 μ g in urban areas. Arsenic levels could be higher in urban areas due to emissions from coal-fired power plants. However, the maximum concentrations measured in a 24-hour period are generally below 100 ng/m³ (ATSDR, 2000). These background values translate into a range of cancer risk estimates between 4×10^{-7} and 1×10^{-5} .

Background arsenic levels in soil in Indiana range from 3.6 to 15 mg/kg, with an average concentration of 7.5 mg/kg (Dragun and Chiasson, 1991).

r50505w.doc

Total cancer risk from a combination of background exposures to arsenic in food, water, air, and soil may be as high as between 10⁻⁴ and 10⁻³ for a substantial portion of the U.S. population.

5.5.2.2 Body Burdens of Arsenic

Soil arsenic has a modest impact on body burden, as evidenced by urinary arsenic levels. Although elevated urinary arsenic levels were reported to be associated with very high soil arsenic levels near copper smelters (Baker et al., 1977; Binder et al., 1987), several studies consistently demonstrated that very low urinary arsenic levels were produced from soil arsenic concentrations below 200 mg/kg. In addition, the Anaconda, MT study demonstrated that urinary arsenic levels were unaffected by soil arsenic levels as high as 500 mg/kg. This observation occurs in part because of the small impact of soil arsenic relative to the impact of background levels of arsenic in food and water.

5.5.2.3 Bioavailability of Arsenic in Soil

Another explanation for the minor impact of soil arsenic on body burdens of arsenic is that arsenic in soil has a relatively low bioavailability and is absorbed into the body (*i.e.*, bloodstream) less efficiently than arsenic in water, the form used by U.S. EPA for the arsenic cancer slope factor. The bioavailability of arsenic in soil depends on two steps: solubilization in gastrointestinal (GI) fluids and absorption across the GI epithelium into the bloodstream (Valberg *et al.*, 1997). Both the solubilization and absorption depend on a variety of factors including the chemical forms of arsenic, the mode of intake by the individual (with or without food, type of food), and the nutritional status, which affects the pH throughout the GI tract, and GI transit time.

The solubility of arsenic depends on soil particle size and the associated soil matrix materials. Particle size affects solubility because larger particles dissolve more slowly than smaller particles, hence, the percentage dissolved during GI transit time increases as particle size decreases. Solubility of arsenic may be limited when insoluble matrix minerals (e.g., quartz) encase arsenic compounds. Similarly, formation of iron-arsenic oxides and phosphates, and prevalence of authigenic carbonate and silicate complexes also limit the solubility of arsenic (Davis et al., 1992, 1996). The solubility in the GI tract is complex since the pH conditions change from low pH in the stomach to a much higher pH in the small intestine. Readily soluble arsenic compounds, such as arsenate and arsenite, are more bioavailable than poorly soluble arsenic compounds, such as arsenic trioxide (ATSDR, 2000).

r50505w.doc

Several animal studies have evaluated the bioavailability of soil-bound arsenic. Results from Freeman et al. (1993 and 1995) and Groen et al. (1994) indicated that soil-bound arsenic is not as bioavailable as arsenic in solution. The bioavailability of soil arsenic relative to aqueous arsenic administered by gavage was approximately 20 percent in monkeys and 48 percent in rabbits. The higher relative bioavailability in rabbits reflected the higher absolute bioavailability in this species. This was much lower than the 64 to 69 percent of arsenic recovered in urine after ingestion of dissolved arsenic by human volunteers (Johnson and Farmer, 1991). Casteel et al. (1997) conducted a multi-year investigation of bioavailability of metals in soil and mine wastes using young swine whose GI system is more similar to humans than other animals. The relative bioavailability of arsenic in soils at various mining and smelting sites ranged from 7 to 52%, which agreed with the results of previous studies by Freeman et al. and Groen et al. Rodriguez et al. (1999) performed a similar swine study that reported the range of 2.7 to 42.8% relative bioavailability of arsenic in soil. Based on Gradient's literature review, a relative bioavailability studies. This evaluation used a relative bioavailability of 80%, based on guidance from USEPA Region 10. The relative bioavailability of 80% is thus likely to overestimate arsenic risks.

5.5.2.4 Cancer Slope Factor (CSF) for Arsenic

Reports on arsenic toxicity in humans are largely based on exposure to arsenic compounds in media other than soil, for example, consumption of drinking water and inhalation in occupational settings. USEPA has derived toxicity factors, *i.e.*, reference dose (RfD) and cancer slope factor (CSF), for ingested arsenic based on data from a Taiwanese study evaluating the health effects associated with the consumption of water containing high concentrations of arsenic (Chen *et al.*, 1985; Tseng *et al.*, 1968). Although the application of the population data used to derive the RfD and CSF has been heavily debated (Carlson-Lynch *et al.*, 1994; Smith *et al.*, 1995; Beck *et al.*, 1995; Mushak and Crocetti, 1995, 1996; Slayton *et al.*, 1996), the values derived are generally believed to be conservative.

The CSF is based on skin cancer observed in a study of over 40,000 people in Taiwan who were exposed for a significant portion of their lifetime to elevated levels of arsenic in groundwater. Although the study clearly indicates an association between high levels of arsenic exposure and cancer, the study design limits its usefulness to derive precise dose-response relationships. The reasons are summarized below:

Exposure Assessment. There are considerable scientific concerns about the exposure estimates in the Taiwanese study (USEPA Region 6, 1998). Individual exposures were not characterized, and exposures were based on average arsenic concentrations of ground water in wells in each village. The amount of exposure was broadly classified into three groups (high, medium and low) and the original data were not available. The analytical method used to measure arsenic concentrations may not be accurate at low levels.

Human-to-Human Variation. In general, dose levels, genetic factors, dietary patterns, or other life style factors may alter arsenic metabolism and detoxification in different populations (USEPA Region 6, 1998). Taiwanese may be more susceptible than U.S. population, and therefore CSF based on Taiwanese population may overestimate cancer for U.S. population. The protein deficiencies in Taiwanese diets could affect their ability to methylate and therefore detoxify arsenic, leading to an increase in cancer risk. Consequently, extrapolation from one population to another becomes highly uncertain.

Other Sources of Exposure. When the U.S. EPA derived the CSF, they did not take into account other possible sources of arsenic in the Taiwanese diet (e.g., from rice and yams) and dietary uses of drinking water. Hence, the assumptions used by the U.S. EPA in deriving toxicity values for arsenic underestimate the total arsenic intake, and as a result, the CSF may overestimate cancer risks.

Non-Linear Dose-Response. A recent U.S. EPA panel concluded that the dose-response for arsenic appeared to be non-linear (USEPA, 1997b), and the U.S. EPA Region 6 concluded that the available data "support a plausible threshold" (USEPA Region 6, 1998). The possible sublinear or threshold dose-response relationship suggests that cancer risk at low doses of arsenic may be less than predicted based on a linear model.

Arsenic Differs in Water and Soil. Health effects associated with arsenic in water may not be relevant to assess the toxicity in soil (Valberg et al., 1997). Arsenic exists in different chemical forms in water and soil, which may lead to potential differences in systemic bioavailability and dose-to-target organ. The relative proportion of overall arsenic intake and the correlation with urinary-arsenic concentrations may also be different between arsenic in water and soil. The differences will ultimately impact the overall potential for adverse health effects.

Overall, these uncertainties limit precise quantification of the dose-response relationship, but suggest the current CSF may overestimate cancer risks for a U.S. population exposed to lower levels of arsenic. Two recently published articles provide evidence that the CSF overestimates the cancer risk for arsenic as applied to drinking water studies outside the U.S. (Guo and Valberg, 1997) and within the U.S. (Valberg *et al.*, 1998). These papers report a meta-analysis of epidemiological studies evaluating the skin cancer incidence of 29 populations in India, Japan, Mexico, Taiwan and the U.S. who were exposed to 1.17 to 270 µg/L arsenic in water. The authors evaluated the validity of U.S. EPA arsenic CSF model to predict the expected number of skin cancers by conducting a likelihood ratio analysis. This analysis showed that a null hypothesis of no additional skin cancer risk from arsenic was approximately two times more likely than the hypothesis of the predicted rate of skin cancer from arsenic. This analysis indicated

that the CSF derived from arsenic exposure in the Taiwanese populations is likely to be an overestimate when applied to the U.S. populations.

Additionally, in the epidemiological studies of a U.S. population that has been exposed to arsenic in drinking water, no increased cancer rate has been observed (USEPA Region 6, 1998). This is further supported by studies of individuals exposed to arsenic in soil who thus far have not indicated any toxicity (Binder *et al.*, 1987; Wong *et al.*, 1992).

5.5.2.5 Summary of Arsenic Risks and Uncertainty

Any effect of arsenic in soil on total arsenic body burden is difficult to observe as a result of the commonly reduced bioavailability of arsenic in soil, and the extent to which soil's contribution to body burden is overwhelmed by background levels of arsenic in food and water. Coupling these considerations with the uncertainty in the derivation of the arsenic cancer slope factor suggest that an acceptable risk level for soil arsenic may be close to 10^{-4} .

5.5.3 Uncertainties in Risk Characterization

Uncertainties associated with the first three steps of the risk assessment (data collection, exposure assessment, and toxicity assessment) are incorporated into the risk estimates in the risk characterization step. Although there are numerous uncertainties associated with this risk assessment, the incorporation of a large number of conservative assumptions has yielded risk estimates that are likely to overestimate actual site risks.

6 Soil Lead Cleanup Levels and Residual Risk

6.1 Soil Cleanup Levels

Lead risks are unacceptable for both construction workers in the main facility area, and the groundskeeper, the future site worker, both construction workers, and the trespasser exposed to sediment in the grassy area. Therefore, soil lead cleanup levels were calculated for these scenarios.

A preliminary remediation goal (PRG) is the average concentration in an exposure area that will result in an acceptable risk to a particular receptor. PRGs are risk-based target cleanup levels that must be met *on average* throughout the exposure area. It is acceptable to leave concentrations that exceed the cleanup level, so long as the post-remediation *average* concentration does not exceed the risk-based cleanup level.

The Remedial Action Level (RAL) is the concentration above which soil must be removed, so that the post-remediation average concentration meets the specified target cleanup level (USEPA, 2001b). The RAL is a remedial action goal (i.e., a remediation trigger concentration) that ensures the post-remediation average concentration at a site achieves the target cleanup level with a specified level of confidence. It is important to note that the PRGs are specific to the receptor and exposure area for which they are developed, and the RALs are calculated with the specific dataset used to derive the EPC for that receptor. Therefore, it would not be appropriate to apply the lowest of all the PRGs or RALs to all of the exposure areas evaluated at the site. If the site was required to have only one PRG applicable to all areas, then all of the site data would need to be combined and assessed as one exposure unit.

According to U.S. EPA guidance, a risk-based cleanup is achieved when the post-remediation average concentration meets the risk-based cleanup level. The goal is to calculate a RAL so that the post-remediation average concentration will achieve the risk-based target cleanup level (the PRG) with a specified level of confidence. Gradient used a Confidence Removal Goal (CRG) algorithm (Bowers et al., 1996)² to determine the RAL. The algorithm has been coded into a computer program which runs in Visual Basic. The CRG algorithm accounts for the inherent uncertainty in characterizing the soil concentration and

39

² Bowers, TS; Shifrin, NS; Murphy, BL. 1996. "Statistical approach to meeting soil cleanup goals." *Environ. Sci. Technol.* 30 (5):1437-1444.

calculates the RAL so that there is a 95% certainty that the average of the post-remediation data (plus the clean replacement fill) will be less than or equal to the PRG. This method is described in USEPA, 2001b.

PRGs for lead are presented in Table 7 for the receptors with unacceptable lead risks. RALs were calculated for these receptors, assuming that excavated soil would be replaced with clean backfill containing lead at 50 mg/kg. In the main facility area, the RAL is 78,900 mg/kg for Construction Worker 1; this scenario assumes that Exide retains the property, and that several small construction projects are conducted over a 5 year period. In the main facility area, the RAL is 8,470 mg/kg for Construction Worker 2; this scenario assumes that the facility is sold and undergoes a one year redevelopment project involving subsurface excavation. In the grassy area, the RALs for surface soil (0 to 6 inches) are 73,900 mg/kg for the Groundskeeper, and 16,655 mg/kg for the Worker. In the grassy area, the RALs for subsurface soil and sediment combined (0 to 30 inches) are 43,300 mg/kg for Construction Worker 1, and 4954 mg/kg for Construction Worker 2. In the grassy area, the RAL for sediment alone is 34,000 mg/kg for the Trespasser. Appendix B shows the sample locations that would be subject to remediation for the scenario with the lowest RAL in each exposure area. The governing lead RAL for each exposure area is presented in Table 8. Appendix B shows that after removal of these samples, and replacement with clean fill, the average of the post-remedial data points is less than the PRG.

Table 8
Governing Lead RAL for Each Exposure Area

| Exposure Area | Media | Receptor | Lead RAL (mg/kg) |
|---------------------------|---------------------------|--|---------------------|
| Onsite Main Facility Area | Soil (0-5 ft) | Construction Worker 1 (Property retained by Exide) | 78,900 |
| Onsite Main Facility Area | Soil (0-5 ft) | Construction Worker 2 (Property sold) | 8,470 |
| Grassy Area | Soil and Sediment (0-6") | Future Site Worker | 16,665 |
| Grassy Area | Soil and Sediment (0-30") | Construction Worker 1 (Property retained by Exide) | 43,300 |
| Grassy Area | Soil and Sediment (0-30") | Construction Worker 2 (Property sold) | 4,954 |
| Grassy Area | Sediment (0-6") | Adolescent Trespasser | 34,000 |

6.2 Post-Remediation Residual Risk

Lead and arsenic concentrations are generally correlated, therefore, rather than calculate PRGs and RALs for arsenic, we considered the effects of lead remediation on the arsenic risks. The residual risk from arsenic was calculated assuming that soil was remediated for lead in the main facility area and the grassy area. Residual arsenic risks were calculated for the receptors that had a cancer risk greater than 1×10^{-5} , or a hazard index greater than 1.0 (Table 9). The post-remediation arsenic data sets are presented in Appendix D. We used the lead RALs that corresponded to the receptors listed in Table 9. The post-remediation arsenic EPCs were calculated (using ProUCL) assuming that excavated soil was replaced with clean backfill containing arsenic at 5 mg/kg (Table 9 and Appendix D). Residual cancer risks range from 1×10^{-6} to 7×10^{-6} , and residual noncancer risks range from 0.03 to 0.2 (Table 9). On the basis of this analysis, PRGs and RALs for arsenic are not needed and were therefore not calculated.

Table 9
Summary of Post-Remediation Risks for Arsenic

| | Pre-I | Remediatio | on | Post-Remediation | | | |
|--------------------------------------|---------------------|----------------|-----------------|---------------------|----------------|-----------------|--|
| Receptor/Exposure Pathway | Arsenic EPC (mg/kg) | Cancer Risk | Hazard Index | Arsenic EPC (mg/kg) | Cancer Risk | Hazard Index | |
| Onsite Construction Worker 2 | (123) | 7E-06 | 1 | 15.9 | 9E-07 | 0.1 | |
| Grassy Area Groundskeeper | 779 | 7E-05 | 0.4 | 49.2 | 4E-06 | 0.03 | |
| Grassy Area Site Worker | 779 | 1E-04/ | 0.7 | 49.2 | 7E-06 | 0.04 | |
| Grassy Area Construction Worker I | 818 | 5E-05 | 2 | 24.0 | 1E-06 | 0.04 | |
| Grassy Area Construction Worker 2 | (818) | 5E-05 | 8 | 24.0 | 1E-06 | 0.2 | |

7 Conclusions

Cancer risks attributable to arsenic were calculated for receptors in five exposure areas. All of the calculated cancer risks fall within or below USEPA's target risk range of 1×10^{-6} to 1×10^{-4} . Cancer risks ranged from 3×10^{-7} to 1×10^{-4} . The exposure scenario with the highest excess lifetime cancer risk is the future site worker in the grassy area (1×10^{-4}). The exposure pathway with the greatest contribution to cancer risk is soil ingestion.

Noncancer risks attributable to arsenic were calculated for receptors in five exposure areas. Noncancer risks exceeded USEPA's target hazard index of 1.0 for the onsite Construction Worker 2; and Construction Workers 1 and 2 in the grassy area. The exposure scenario with the highest noncancer risk is the grassy area Construction Worker 2 (HI of 7.6). The exposure pathway with the greatest contribution to noncancer risk is soil ingestion.

Lead risks were evaluated for adult and/or adolescent receptors in five exposure areas. Lead risks were evaluated by comparing the predicted fetal BLL for each receptor to USEPA's BLL goal of 10 µg/dL. Predicted 95th percentile fetal BLLs exceeded USEPA goals for the following receptors: Construction Workers 1 and 2 in the main facility area, the groundskeeper and future site worker exposed to surface soil in the grassy area, Construction Workers 1 and 2 exposed to subsurface soil in the grassy area, and the Trespasser exposed to sediment in the grassy area. The predicted 95th percentile fetal BLL did not exceed the USEPA goal for the following receptors: the Utility Worker in the main facility area, the Trespasser exposed to soil in the grassy area, the Recreator in the Railroad Ditch, the Recreator along Arlington Ave, and the Offsite Gas Facility Worker.

PRGs and RALs were calculated for lead, for the receptors with unacceptable lead risks. In the main facility area onsite, the RAL is 78,900 mg/kg for Construction Worker 1, and 8,470 mg/kg for Construction Worker 2. For grassy area surface soil, the RAL is 73,900 mg/kg for the Groundskeeper, and 16,655 mg/kg for the Site Worker. For grassy area subsurface soil and sediment combined, the RAL is 43,300 mg/kg for Construction Worker 1, and 4954 mg/kg for Construction Worker 2. For the grassy area sediment alone, the RAL is 34,000 mg/kg for the Trespasser.

The residual risk from arsenic was calculated assuming that soil was remediated for lead in the main facility area and the grassy area. Residual cancer risks range from 9×10^{-7} to 7×10^{-6} . Residual

noncancer risks range from 0.03 to 0.2. All post-remediation residual risks for arsenic are within or below EPA's target risk range for cancer and non-cancer risks.

NHANES 2000 Blood Lead Data

NHANES 2000 Blood Lead Data

The NHANES blood lead data for 1999-2000 were downloaded from the following website:

http://www.cdc.gov/nchs/about/major/nhanes/nhanes99_00.htm

The blood lead data are in the file: "Lab 06 Nutritional Biochemistries". The demographic data are in the file: "Demographics".

The demographic and blood lead data were merged on the variable "SEQN".

Attached are the following documents:

- The SAS Code used to calculate the blood lead summary statistics from NHANES-2000
- The SAS output with the blood lead summary statistics
- Pages from the CDC NHANES-2000 Website

```
Analyze blood lead data from NHANES-2000.

Release Notes

NCHS releases public use data sets from the continuous NHANES in two year groupings (cycles). This release does not contain all of the data collected on persons who participated in the survey during those two years (9,965 persons). As more data becomes available it will be released on this webpage. These updates will be documented on this site. Data processing, methodologic and disclosure concerns are examples of the reasons why various data components from NHANES 1999-2000 are not on this first public use data release. When (and if) these concerns are resolved, the data will be made publicly available.

For a number of reasons, the release of data from the current

NHANES will not be comparable to the approach used in previous NHANES studies. The data and documentation for the interview, laboratory and examination components of the survey will be released in numerous files to facilitate ease of use and access via the Internet. This will require the user to merge files to create analytic data sets. In addition, changes in the survey design and implementation necessitate analytic guidelines that differ from previous NHANES. Many of the past general analytic principles still apply, but with adjustments for the new survey design and taking into account more recent statistical practices and procedures. The guidelines will be revised on various occasions as new issues are raised and addressed by NCHS staff. Users are encouraged to regularly check this site for updates on available data, documentation and guidelines for use of the data.

NHANES data in this release are in SAS transport file format. To access this data in any version of SAS, use the XPORT engine. It is recommended that you copy the transport files to a permanent SAS library. For example, assuming you have downloaded the Body Measures exam data to the folder "C:\NHANES", you can use the following SAS code to copy the Body Measures Exam Data:

LIBNAME XP XPORT "C:\NHANES\BMX.XPT"; PROC COPY IN=XP OUT=SASUSER; RUN;

NHANES documentation and codebooks are in Adobe Acrobat PDF. If you do not have a current version of Acrobat Reader, a free copy may be obtained from the **Adobe web site**.

Refined Metals Corporation Beech Grove, Indiana

Dear Mr. Adenuga,

Please find enclosed Refined Metal Corporation's (Refined's) responses to EPA comments dated August 17, 2004 regarding the Corrective Measures Study Report Phase I and a revised copy of that report which incorporates EPA's comments and Refined's responses.

I certify under penalty of perjury that the information contained in or accompanying the enclosed response to comments and revised report is, to the best of my knowledge after thorough investigation, true, accurate, and complete. I am aware that there are significant penalties for submitting false information, including the possibility of fine and imprisonment for knowing violations.

Sincerely,

REFINED METALS CORPORATION

Matthew A. Love

- Corrective Measures Study Activities Summary Report Baseline Human Health Risk Assessment 1
- 2

1.0 INTRODUCTION

Presented herein, is the revised Phase I Corrective Measures Study (CMS) Report for the Refined Metals Corporation (RMC) facility in Beech Grove, Indiana. Pursuant to the CMS Work Plan, approved by USEPA in a letter dated November 5, 2003, this report has been prepared to present the results of the additional sampling activities and the preliminary risk assessment results. It has been revised to reflect the comments made by the USEPA in a letter dated August 17, 2004 on the initial version of this letter. A description of the activities is provided in the following sections. Copies of the revised CMS Activities Summary Report and revised Baseline Human Health Risk Assessment are provided as attachments.

2.0 FIELD ACTIVITIES

Based on an evaluation of previous investigation results following the Phase II RCRA Facility Investigation (RFI), a determination was made that additional characterization sampling was required for sediment and groundwater at the RMC Site. The sediment sampling consisted of collecting additional samples from the drainage ditch along the CSX Transportation railroad right-of-way north of the facility and from the grass lined drainage ditch along the west side of Arlington Avenue. Sediment samples were collected from six locations along the railroad drainage ditch and four locations in the Arlington Avenue drainage ditch. Two samples were collected at each location. Along Arlington Avenue, one sample was collected from the 0 to 6inch depth and the second from the 6 to 12-inch depth. Along the railroad right-of-way, they were collected from 0 to 3 inches and 3 to 10 inches. The depth of the railroad samples was consistent with the requirements for soil samples, although they were intended to be consistent with the 0 to 6-inch and 6 to 12-inch depths for sediment samples. The change in depth was inadvertent and was not detected until review of sampling logs after the completion of sampling. For the metals included in the analysis, the shallower depths likely provide higher concentrations in the 0 to 3-inch and 3 to 10-inch samples when compared to a 0 to 6-inch sample or 6 to 12inch sample, respectively, from the same location.

Groundwater sampling included the installation of three piezometers in the area north and east of the former manufacturing area. The piezometers were installed with the intent of further refining groundwater flow direction prior to selection of locations for the new monitoring wells. The piezometers were allowed to set for 24 hours before groundwater level measurements were taken from the existing shallow monitoring wells at the north end of the former manufacturing area and the piezometers. Groundwater flow direction was re-assessed based on the measurements and the locations for two new groundwater-monitoring wells were selected. The new groundwater monitoring wells were installed using hollow stem auger (HSA) drilling techniques. The piezometers were abandoned after groundwater level measurements were taken. Groundwater samples were collected from all the Site groundwater monitoring wells between October 26 and 28, 2004 using low flow sample collection techniques.

A complete description of the sediment and groundwater sampling activities is provided in the revised Phase I CMS Activities Summary Report which is provided as Attachment 1 to this report.

3.0 ANALYTICAL RESULTS

3.1 GROUNDWATER

Shallow groundwater at the Site is perched and discontinuous and is not used for any purpose. Groundwater samples collected from the shallow groundwater monitoring wells in the north end of the former manufacturing area (MW-2, 7 and 8) gave unfiltered results for total lead in excess of the Indiana Department of Environmental Management (IDEM) Residential Default RISC Criteria (15 ug/L). Analysis of filtered groundwater samples from those wells for lead from the same sampling event were at or below the IDEM Residential Default RISC Criteria. Filtered and unfiltered results for arsenic in MW-1, MW-2, MW-7 and MW-8, and unfiltered results only for MW-3, MW-5 and MW-10 were above the background concentration for arsenic (8.5 µg/l) calculated in the Phase II RFI. No other parameters for MW-2, MW-7 and MW-8 or any of the parameters analyzed for any other well on-site exceeded the IDEM Residential Default RISC Criteria.

3.2 SEDIMENT

Concentrations of lead in the shallow surface sediment samples collected at the depth of 0-3 inches ranged from 617 mg/kg to 14,800 mg/kg and concentrations or arsenic ranged from 12 mg/kg to 169 mg/kg at this depth. Concentrations of lead in the shallow surface sediment samples collected at the depth of 0-6 inches ranged from 411 mg/kg to 874 mg/kg and concentrations of arsenic ranged from 11 mg/kg to 12 mg/kg at this depth. The calculated background for arsenic in shallow surface soil (10.5 mg/kg) was exceeded in all samples. The cleanup level for lead calculated in the Human Health Risk Assessment (Attachment 2)(15,916 m/kg) was not exceeded in these samples.

Concentrations of lead in the subsurface sediment samples collected at the depth of 3-10 inches ranged from 403 mg/kg to 15,700 mg/kg and concentrations of arsenic ranged from 9 mg/kg to 216 mg/kg at this depth. Concentrations of lead in the samples collected at the depth of 6-12 inches ranged from 24 mg/kg to 1,470 mg/kg and concentrations of arsenic ranged from 8.3

mg/kg to 15 mg/kg at this depth. The calculated background concentrations for arsenic in subsurface soil (7.9 mg/kg) was exceeded in all samples. The calculated cleanup level for lead (15,916 mg/kg) was not exceeded in these samples.

4.0 PRELIMINARY RESULTS OF RISK ASSESSMENT

Gradient Corporation (Cambridge, MA) conducted the Baseline Human Health Risk Assessment (Risk Assessment) for RMC. Pursuant to the CMS Work Plan, the Risk Assessment evaluated a variety of exposure scenarios for lead and arsenic for workers at the facility and on the adjacent Citizens Gas property. The evaluation determined that the calculated risk for existing arsenic levels at the Site are within the USEPA target risk ranges for the exposure scenarios evaluated. The lead risk evaluation determined that soil lead concentrations in some areas of the Site create a predicted (95% UCL) blood lead >10ug/dl for the construction worker in the "on-site" area, and for the groundskeeper and plant worker in the "grassy area".

Results of the risk assessment for lead include a Preliminary Remediation Goal (PRG) for each of the exposure scenarios which predict a 95% UCL blood lead >10 ug/dl. The model also provides a Remedial Action Level (RAL), which represents the soil cleanup concentration that will result in remaining soil having an average soil lead concentration less than the PRG. The concept of a RAL is consistent with the adult lead model, which recognizes that the model evaluates exposure on an area wide basis. This means that soils with concentrations exceeding 78,900 mg/kg must be remediated in the "on-site" area to result in an average lead concentration less than 4,601 mg/kg. For the grassy site area (which also includes the wooded areas), the PRG and RAL are 3,195 and 16,700 mg/kg, respectively. The PRG for the Citizens Gas property is 1,840 mg/kg, which is higher than the average soil lead concentration; therefore, no remediation is necessary on the Citizens Gas property.

The complete Baseline Human Health Risk Assessment report is provided as Attachment 2.

5.0 CONCLUSION

Based on the results of the Risk Assessment, risk estimated for arsenic fall within the USEPA target risk range and the totoal hazard index are all well below 1.0. Based on this analysis, no soil remediation is believed to be necessary for arsenic.

A conclusion of the Baseline Human Health Risk Assessment is that soil remediation is necessary in the "on-site" plant area to remove subsurface soil with total lead concentrations that exceed the calculated RAL of 78,900 mg/kg. Because the exposure scenario assumes a worker who is performing intrusive activities, this standard is being applied to areas with and without pavement.

For the "grass areas", which includes all areas of the site excluding the "on-site" area, the RAL is 16,700 mg/kg for surface soils and no remediation is required for subsurface soils (i.e., soils deeper than 6 inches). Additionally, because the exposure scenario anticipates a non-intrusive use, no removal will be proposed beneath areas of existing pavement. The drainage ditches are considered to be part of the "grass areas" and will therefore be remediated to the 16,700 mg/kg RAL.

Additional sediment sampling is proposed in the drainage ditch that drains around the west side of the Citizens Gas property from the railroad right of way. A description of the proposed sampling is provided in the CMS Activities Summary Report.

LIST OF APPENDICES

APPENDIX

- A Geoprobe and Monitoring Well Logs
- B Sediment Sampling Data October 2003 Groundwater Data

1.0 INTRODUCTION

1.1 GENERAL

This Corrective Measures Study Activities Summary Report has been submitted by Advanced GeoServices Corp. (AGC) on behalf of Refined Metals Corporation (RMC). This report presents and discusses the methods and procedures used to implement the scope of work as proposed in the Phase II RCRA Facility Investigation (RFI) Report. Groundwater monitoring well installation and sampling activities were conducted by AGC. These activities consisted of installing three piezometers and two groundwater monitoring wells, groundwater sampling and sediment sampling at on-site and off-site locations. Laboratory sample analysis was performed by TriMatrix Laboratories Inc. (TriMatrix) of Grand Rapids, Michigan.

The RMC facility was the location of secondary lead smelting operations from 1968 through 1995. RMC was involved in the reclamation of lead from used automotive and industrial batteries and other lead bearing materials. The Site ceased smelting operations on December 31, 1995. Additional background and facility operation can be found in the Phase II RCRA Facility Investigation Report, dated November 18, 2002.

During its operational life, the facility handled materials that were classified as hazardous materials or hazardous wastes under the Resource Conservation and Recovery Act (RCRA). At this time, the Site is idle except for the wastewater treatment system which remains in operation. The wastewater treatment system remains in place to collect and treat stormwater runoff from the lined lagoon and other Site areas.

2.0 WELL INSTALLATION ACTIVITIES

2.1 <u>INTRODUCTION</u>

Background and facility operation information can be found in the Phase II RCRA Facility Investigation Report, dated November 18, 2002. During the Corrective Measures Study (CMS) three temporary piezometers and two groundwater monitoring wells were installed by Boart Longyear, Environmental Division, from Greensberg, Indiana. The three piezometers were installed using a truck mounted Geoprobe in the area north and east of the former manufacturing area. The piezometers were installed for the purpose of refining groundwater flow prior to selection of locations to install two new wells. Geoprobe borings were advanced into the shallow perched groundwater and the piezometer was constructed using a one (1) inch diameter PVC 0.010 screen. The piezometers were constructed on September 4, 2003 as follows:

| | Depth of | Depth of | Screen | GW Elevation |
|------|----------|------------|--------|--------------|
| | Boring _ | Piezometer | Length | 9/05/2003 |
| GP-1 | 20' | 18.0' | 15' | 837.63 |
| GP-2 | 15' | 14.8' | 10' | 839.30 |
| GP-3 | 25' | 23.5' | 15' | 877.89 |

Groundwater level measurements were taken from the existing monitoring wells north of the former manufacturing area and piezometers on September 5, 2003 and the locations for two new groundwater-monitoring wells were selected.

The two groundwater monitoring wells were installed between September 8-10, 2003 and designated as MW-10 and MW-11. Groundwater monitoring well MW-10 is located east of MW-2 within the wooded area as shown on Figure 2-1. The depth of the boring for MW-10 was recorded to be 36 feet below ground surface (bgs). Groundwater monitoring well MW-11 is located approximately 156 feet east of MW-8 along the fence line of Arlington Avenue. The

depth of the boring for MW-11 was measured at 30 feet bgs. The locations of both wells installed are shown on Figure 2-1.

2.1.1 Drilling Methods

The soil borings were advanced using hollow stem auger (HSA) techniques and continuous split spoon samples were collected in accordance with ASTM D 1586. The logs for the borings and well construction completed as part of this investigation are included in Appendix A. The samples recovered from the advancement of the deep borings were logged and described using USCS soil classification.

2.1.2 Groundwater Monitoring Well Construction

The monitoring wells were constructed using a 4-inch ID, flush-threaded, Schedule 40 PVC riser with a 10-foot length of factory-slotted 0.010-inch PVC well screen. A sand pack was placed to 2 feet above the top of the monitoring well screen with No. 5 sand. A minimum 2-foot thick bentonite seal was placed on top of the sand pack.

All monitoring wells were completed with a steel protective casing with a locking cap. The protective casing extends from an approximate depth of 3 feet bgs to approximately 2 feet above ground. A neat cement seal was placed around the protective casing to a depth of 2.5 to 3 feet bgs. A 2-foot square well pad was installed so that the surface slopes away from the well.

2.1.3 Groundwater Monitoring Well Development Method

Each groundwater monitoring well installed as part of this Corrective Measures Study field activities were developed using the surge-block and pump method. Groundwater monitoring wells were first surged using a plunger-type surge block assembly. This provides the necessary turbulence in and immediately surrounding the well screen to remove fine-grained material. The wells were then purged and developed by continuous pumping using a electric submersible

pump. Well development ceased when the development water in each well was relatively sediment free, exhibited a satisfactory visual clarity and yield.

2.2 GROUNDWATER SAMPLING

2.2.1 Groundwater Well Evacuation

Following the installation of the two additional groundwater monitoring wells, groundwater samples were collected. The sampling event took place on October 26-29, 2003. Groundwater samples were obtained from groundwater monitoring wells MW-1, MW-2, MW-3, MW-4, MW-5, MW-6SR, MW-7, MW-8, MW-9, MW-10 and MW-11. A total of 11 groundwater samples were collected at the Site (excluding QA/QC samples). A low-flow sampling technique was employed to more accurately determine the potential for site-related constituents which may have entered the groundwater.

Each groundwater monitoring well was purged using a stainless steel low-flow bladder pump placed at the midpoint of the screen in each well. The wells were purged at a flow rate ranging from 100 to 300 milliliters per minute mls/min, depending on the yield of the well. A flow-through cell was used to measure the following field parameters: pH, temperature, conductivity, redox potential, and dissolved oxygen prior to contact with oxygen. These parameters were collected at 3 to 5 minute intervals during purging event. Turbidity was also measured at the same time interval. The wells were purged until the field parameters stabilize to within 10% over three readings and pH readings differ by less than 0.1 unit.

2.2.2 Groundwater Sample Collection

Once the field parameters had stabilized, samples were collected directly from the pump discharge line into laboratory-supplied bottles containing the necessary preservatives at a sampling flow rate of 100 to 300 mls/min.

Sample containers were labeled with a unique identifying number, time and date of sample collection, requested analysis, preservative, and the initials of the sample collector. Samples were packed on ice and shipped to TriMatrix Laboratories Inc. for analysis of eight RCRA metals and antimony (SW-846 6010). Samples for dissolved metals analyses were field filtered through a dedicated disposable Nalgene 0.45 µm membrane filter immediately after collection and prior to preservation. The sample was decanted into the dedicated, Nalgene disposable filtration unit and filtered under vacuum pressure created by a hand-held pump. The sample was then immediately transferred to a laboratory supplied bottleware.

3.0 SEDIMENT SAMPLING

Sediment samples were collected from four locations along the drainage ditch running parallel to Arlington Avenue and from six locations along the CSX rail line drainage ditch. The samples collected along the Arlington Avenue drainage ditch were designated R2SED-11 through R2SED-14. The samples collected along the CSX line were designated R2SB25 through R2SB-30. The location of the sediment samples are presented on Figure 3-1. The CMS Work Plan specified collection of two sediment samples from each location at depths of 0 to 6 inches and 6 to 12 inches. Along Arlington Avenue, the samples (designated R2SED-11 through R2SED-14) were collected from the 0 to 6-inch depth and the 6 to 12-inch depth as specified for sediment samples. Along the CSX railroad right-of-way, the samples (designated R2SB25 through R2SB-30) were inadvertently collected following the sample intervals utilized for soil sampling of 0 to 3 inches and 3 to 10 inches. The deviation was not identified until after the completion of sampling activities. The data has been retained and presented in this report, however the results are likely biased towards a higher concentration than the intended sample depths would have This is because off-site sediment impacts from facility operations are likely produced. attributable to stormwater runoff and/or air deposition and because metals are not expected to migrate vertically any applicable distance. For this reason, it is expected that impacts from facility operations would be greater near the surface and would relapse rapidly with depth.

The depth of collection was placed as a suffix to each sample location to delineate in which depth the result is correlated. All sediment samples were collected using decontaminated hand augers. The sediment from each interval was thoroughly homogenized in an aluminum mixing pan and was placed directly into a laboratory supplied jar. Each sediment sample was then placed on ice for shipment and was submitted to TriMatrix to be analyzed for arsenic and lead (EPA Method SW-846 6010B).

4.0 RESULTS

4.1 GROUNDWATER

4.1.1 Groundwater Screening

Arsenic and lead are the two site constituents of concern (COCs) that were detected at levels above the concentrations used for initial groundwater screening purposes. A background concentration was calculated for initial screening of arsenic in groundwater. The background concentrations for arsenic in groundwater has been calculated to be $8.5~\mu g/l$, which is the mean concentration taken from MW-9 plus one standard deviation. The current EPA Region 9 Preliminary Remediation Goals for Tap Water do not provide a standard for lead in groundwater; therefore, we are utilizing the Indiana Department of Environmental Management (IDEM) Residential Default RISC criteria of 15 $\mu g/l$. The IDEM Residential Default RISC criteria for arsenic is 50 $\mu g/l$.

4.1.2 Groundwater Sampling Results

The analytical results for samples collected from the on-site wells for the groundwater sampling event are presented in Table 4-1. A groundwater surface map is shown as Figure 4-1. October 2003 sample results are provided in Figure 4-2.

Total arsenic was found in groundwater samples at concentrations ranging from 1.3 μ g/l in MW-4 to 290 μ g/l in MW-7. Arsenic concentrations were detected above the background concentration in MW-1 (24 μ g/l), MW-2 (15 μ g/l), MW-3 (28 μ g/l), MW-5 (8.8 μ g/l), MW-7 (290 μ g/l), MW-8 (19 μ g/l) and MW-10 (24 μ g/l). Only MW-7 exceeded the IDEM Residential Default RISC Criteria for arsenic in groundwater.

Total lead was found in groundwater samples at concentrations ranging from below laboratory detection level in MW-1, MW-3, MW-4, MW-10, and MW-11 to 217 μ g/l in MW-7. Lead concentrations were detected above the IDEM Residential Default Risk Criteria concentration in MW-2 (44 μ g/l), MW-7 (217 μ g/l) and MW-8 (55 μ g/l). The only filtered sample at or above 15 μ gl was MW-8 at a concentration of 15 μ gl.

4.2 <u>SEDIMENT</u>

4.2.1 <u>Sediment Screening</u>

Arsenic and lead are the two site constituents of concern (COCs) that were detected at levels above their initial screening levels for soil and sediment. Samples collected from the drainage ditches are referred to as sediment in this report; however, because of the physical character of the material sampled and geomorphic setting, they are compared to the soil standards. The calculated background arsenic in soil concentrations are 10.53 mg/kg for surface soil (0-3 inch) and 7.91 mg/kg (>3 inches) for subsurface soils. Based on the Baseline Human Health Risk Assessment (Attachment 2), the target cleanup level for lead in soil at the Site is 15,916 mg/kg for surface (0-6 inches) soil.

4.2.2 Sediment Sampling Results

The validated analytical results for the sediment samples collected within the drainage ditch along Arlington Avenue and the drainage ditch along the CSX rail line are provided in Table 4-2, and a copy of the validation report is provided in Appendix B.The depth of collection was placed as a suffix to each sample location to delineate to show to which depth the result is correlated.

Concentrations of lead in the samples collected at the depth of 0-3 inches ranged from 617 mg/kg at R2SB25 to 14,800 mg/kg at R2SB29, and concentrations of arsenic ranged from 12 mg/kg at R2SB30 to 169 mg/kg at R2SB26 at this depth. The calculated background concentration for

arsenic was exceeded in all samples. The Baseline Human Health Risk Assessment (HHRA) cleanup level for lead was not exceeded in these samples.

Concentrations of lead in the samples collected at the depth of 0-6 inches ranged from 411 mg/kg at R2SED-12 to 874 mg/kg at R2SED-11, and concentrations of arsenic ranged from 11 mg/kg at R2SED-14 and R2SED-12 to 12 mg/kg at R2SED-11 and R2SED-13 at this depth. Table 4-2 presents lead and arsenic results within this depth interval. The calculated background concentration for arsenic was exceeded in all samples. The HHRA cleanup level for lead was not exceeded in these samples.

Concentrations of lead in the samples collected at the depth of 3-10 inches ranged from 403 mg/kg at R2SB28 to 15,700 mg/kg at R2SB29, and concentrations of arsenic ranged from 9 mg/kg at R2SB30 to 216 mg/kg at R2SB29 at this depth. Table 4-2 presents lead and arsenic results within this depth interval. The calculated background concentration for arsenic was exceeded in all samples. The HHRA cleanup level for lead was not exceeded in these samples.

Concentrations of lead in the samples collected at the depth of 6-12 inches ranged from 24 mg/kg at R2SED-14 to 1,470 mg/kg at R2SED-11, and concentrations of arsenic ranged from 8.3 mg/kg at R2SED-13 to 15 mg/kg at R2SED-11 at this depth. The calculated background concentration for arsenic was exceeded in all samples. The HHRA cleanup level for lead was not exceeded in these samples.

5.0 **SUMMARY**

The following are drawn from the findings of the Corrective Measures Study activities:

Groundwater

- Thin discontinuous zones of higher permeability glacial soils in (sand) clayey silt and silty clay characterize the shallow zone of saturation.
- Potentiometric groundwater maps for the shallow wells indicate a high point in the vicinity of MW-1. Those maps also show a trough in the groundwater surface oriented north-south through MW-8, MW-6SR and MW-4. The presence of the trough is believed to be the result of the discontinuous semi-confined zones of saturated sand or a groundwater mounded created by periodic standing water in the flat lawn area between the paved manufacturing areas and Arlington Avenue.
- Arsenic concentrations exceeded the calculated background concentration in all but four of the samples tested.
- Lead detected above the IDEM Residential Default RISC Criteria is limited to MW-2S (18 μg/l), MW-7S (217 μg/l) and MW-8S (28 μg/l) immediately north of the manufacturing area where elevated soil lead concentrations exist.

Sediment

• Elevated arsenic in sediment in the drainage ditch along the CSX line northeast of the Site indicate that off-site transport of sediment has probably occurred. To further delineate these impacts, additional sediment samples shall be collected from the drainage channel that begins at the rail road right-of-way between RS2B-26 and RS2B-27 and flows across the Citizens Gas property. Nine (9) additional

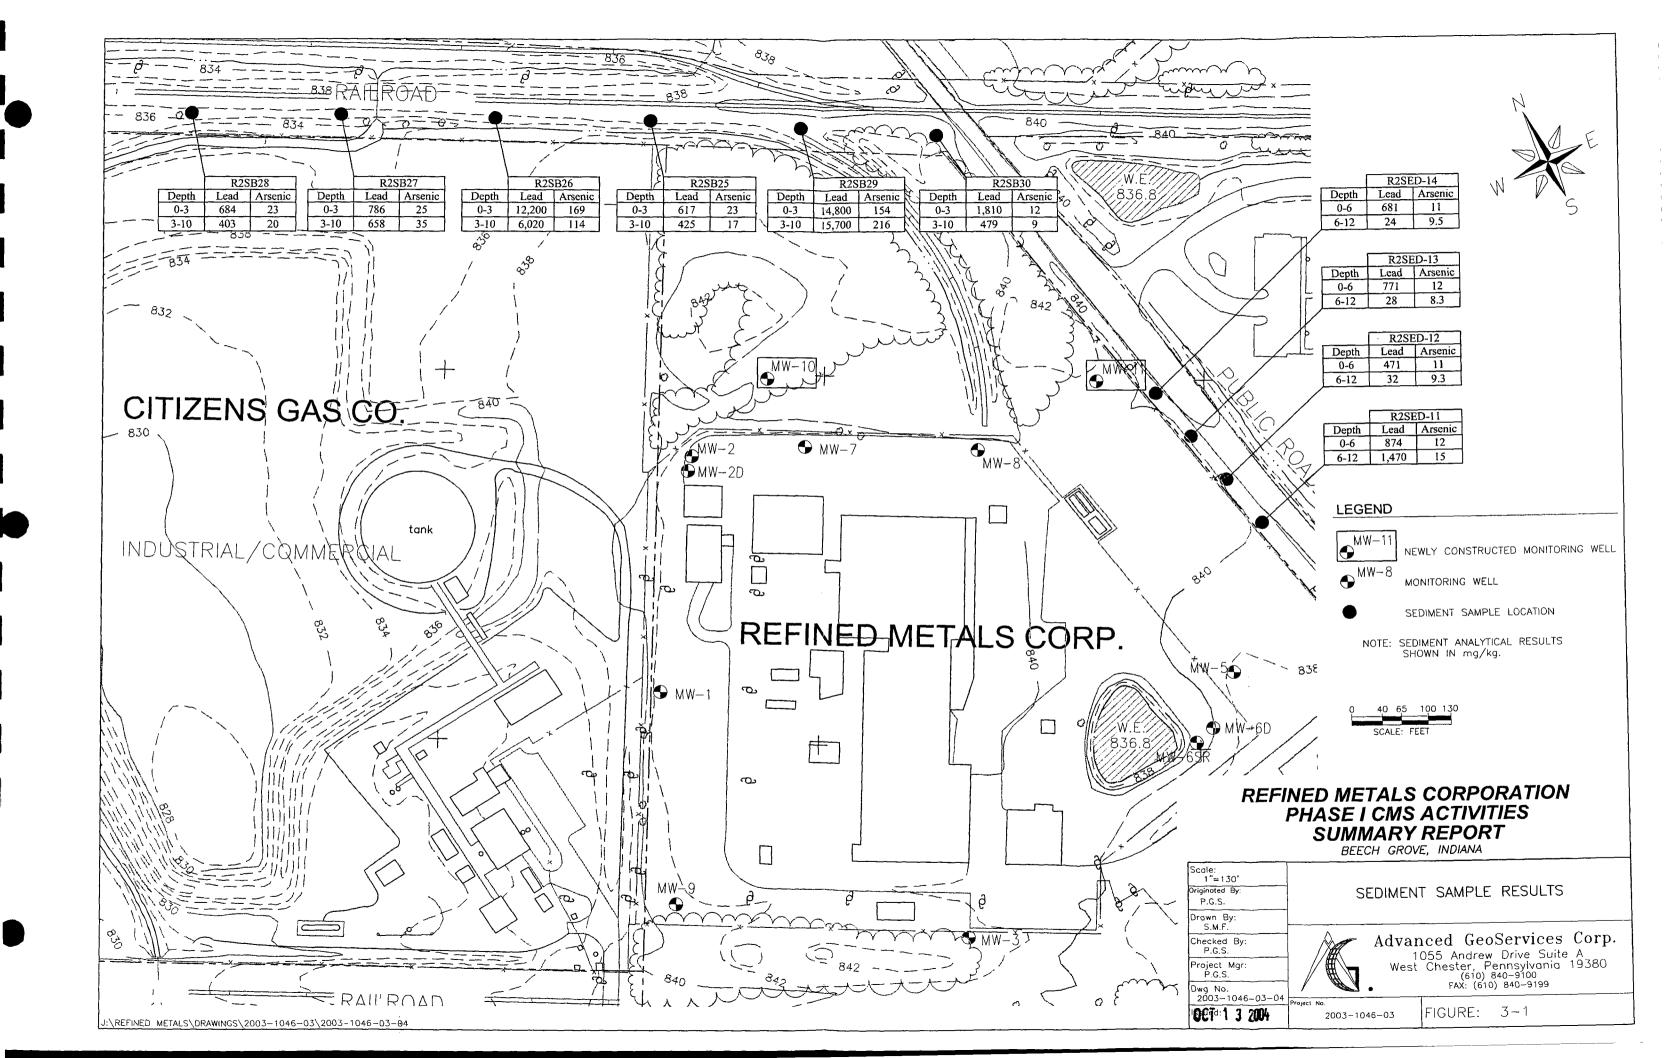

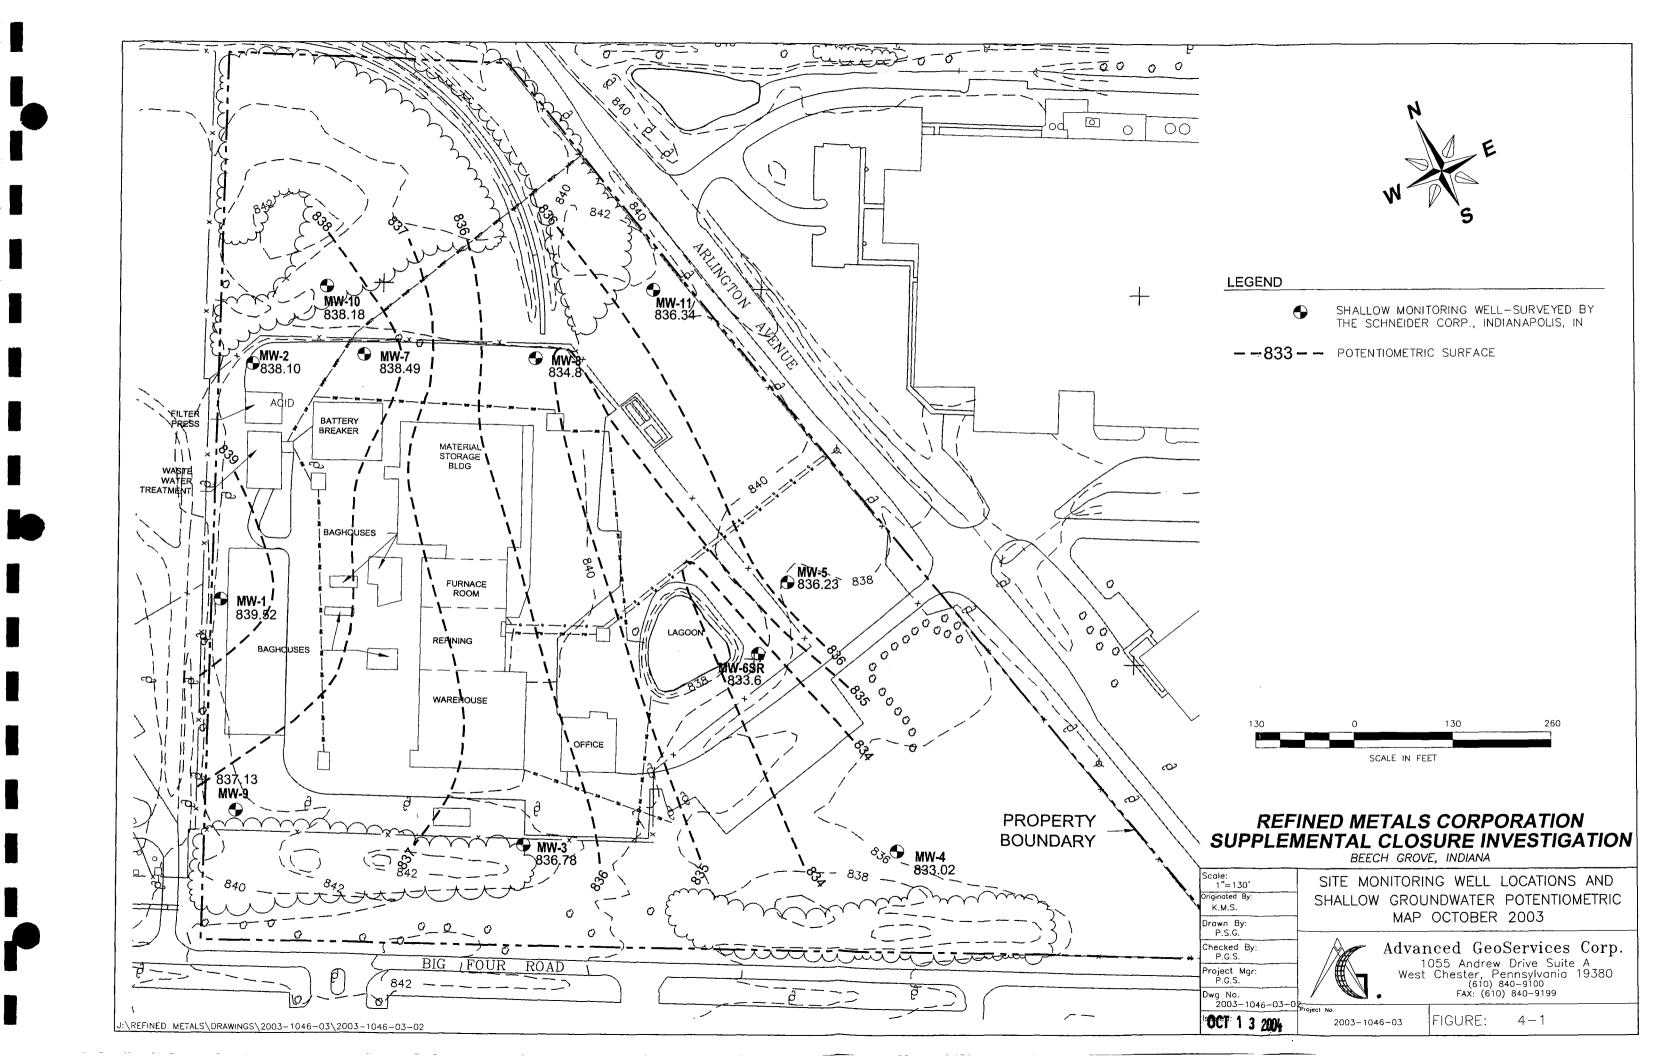

locations will be sampled. Similar to sediment samples previously collected along the CSX line, the samples will be uniformly distributed at approximately 200 feet on-center. Sampling will be performed following the criteria established for sediment samples in the Phase 2 RFI Work Plan.

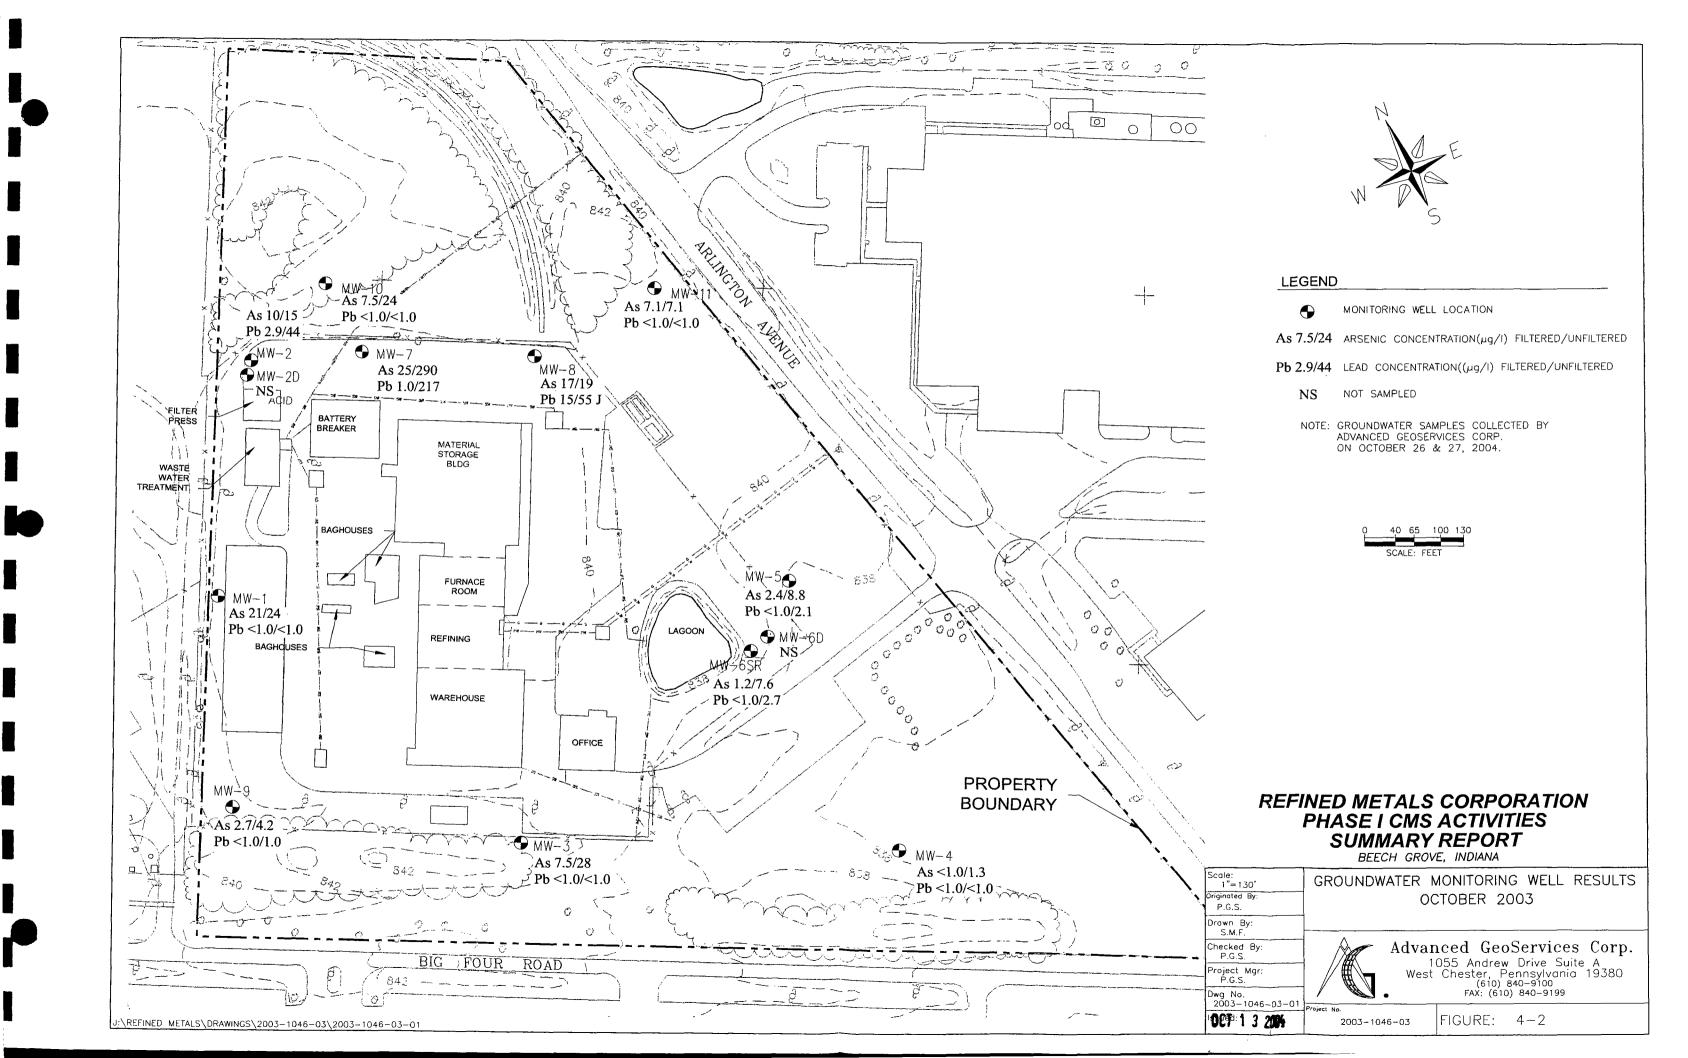

- The most downstream sediment samples from the grass lined swale along Arlington Avenue are below 100 mg/kg total lead. Based on this result no additional sampling is proposed along Arlington Avenue.
- All sediment sample results for lead are shown to be below the RAL calculated in the Baseline Human Health Risk Assessment.

1 Introduction

1.1 Site Description and History

The Refined Metals Corporation (RMC) facility is located at 3700 South Arlington Avenue in Beech Grove, Indiana. Secondary lead smelting and refining operations were conducted at this site from 1968 to the end of 1995.

The site occupies approximately 24 acres, of which approximately 10 acres represented the active manufacturing area (including paved areas and buildings). The remaining 14 acres includes grassed and wooded site areas. The site is bordered by Arlington Avenue to the east, a natural gas facility (Citizen's Gas) to the west, a railroad to the north, and Big Four Road to the south (Figure 1). The site is relatively flat with less than 10 feet of total relief. Natural site drainage is toward the north and east. The former manufacturing area is almost completely paved, and is characterized by nearly 80,000 square feet of structures consisting of the battery breaker, a wastewater treatment plant, material storage areas, a blast furnace, a dust furnace, a metals refining area, warehouse and offices.

The RMC facility was divided into two exposure areas for the purpose of this evaluation: the fenced facility area consisting of the plant buildings and surrounding paved areas; and the grassy areas to the north, east, and south of the paved facility area. The Citizen's Gas property to the west was evaluated as a separate exposure area.

1.2 Previous Investigations

On July 14, 1998, RMC entered into a Consent Decree with the United States Environmental Protection Agency (USEPA) and the Indiana Department of Environmental Management (IDEM). Under this Consent Decree, a RCRA Facility Investigation (RFI) was performed to evaluate and determine the nature and extent of releases and to collect information necessary to support human health and ecological risk assessments so that a Corrective Measures Study may be implemented. Pursuant to Section VI, Paragraph 42 of the Consent Decree (Compliance Requirements for Corrective Action), Advanced GeoServices Corp. (AGC) performed the RFI in accordance with an approved RFI work plan on behalf of RMC. The preparation and implementation of the RFI work plans were enacted in accordance with Exhibit B of the Consent Decree and the EPA's RCRA Facility Investigation Guidance Document (EPA 530/SW-89-031). The RFI was conducted in multiple phases. The results from the initial phase of

sampling were presented in the Phase I RFI Report dated August 31, 2000 (AGC, 2000). Based on the results of the Phase I RFI a Phase II RFI Work Plan was submitted to the EPA on December 20, 2000. In response to comments on the Phase II RFI Work Plan issued by the EPA on April 3, 2001, revisions to the Phase II RFI Work Plan were submitted to the EPA on June 27, 2001. The EPA approved the Phase II RFI Work Plan on July 13, 2001, the results of which were contained in the Phase II RFI Report dated November 18, 2002 (AGC, 2002). Additional site sampling was conducted during a closure investigation to address three former RCRA-regulated solid waste managements units (SWMUs). The results of the SWMU closure investigation were presented by AGC in the Closure Investigation Report dated June 1, 2001.

1.3 Report Objectives and Organization

This report presents the results of the baseline human health risk assessment (HHRA) that was conducted to evaluate potential human health risks in each exposure area. The purpose of this evaluation is to determine whether these areas pose any significant health risks or if they require remediation to reduce risk to acceptable levels.

The remainder of this report is organized in the following sections. Section 2 discusses the data used in the risk assessment, and the constituents of potential concern. Section 3 discusses the potential receptors, exposure media, and exposure pathways for each exposure area. Section 4 presents the toxicity assessment. Section 5 presents the risk characterization. Section 6 presents soil lead cleanup levels. Section 7 presents the conclusions for all scenarios evaluated.

2 Constituents of Potential Concern

The results of the Phase I RFI indicated that lead and arsenic are the main contaminants of concern in soil, both onsite and offsite. Lead and arsenic were detected in soil samples from the site at concentrations above both residential and industrial risk-based concentrations (RBCs). The baseline risk assessment retained lead and arsenic as COPCs in soil.

3 Exposure Assessment

3.1 Potential Receptors and Exposure Pathways

The potential receptors, exposure media, exposure pathways, and exposure frequencies evaluated in each exposure area are presented in Table 1, and are discussed in more detail below. Exposure Areas are shown in Figure 1.

Table 1
Receptors and Exposure Pathways

| Exposure Area | Media | Soil Depth | Exposure Pathways | Receptors | Exposure Frequency (days/year) | Exposure Duration (years) |
|-------------------------------------|-----------------|---------------|---------------------------------|--------------------------|--------------------------------------|---------------------------------|

| South, and East Grassy | Surface soil | 0-6" | Dermal Contact | Adolescent Trespasser | 25 | 5 |
| Areas | | | Comaci | Future Site Worker | 144 | 25 |
| Off Site Natural Gas Facility | Surface soil | 0-6" | Ingestion, Dermal Contact | Adult Worker (30 yr) | 225 | 25 |

3.1.1 Facility Area

The plant buildings and surrounding paved areas occupy approximately the central third of the RMC property. The site is largely paved – the only exposed surface soil is limited to a strip along the western fence line. In this exposure area, we evaluated a utility worker and a construction worker who could be exposed to subsurface soil. Both the utility and construction worker are assumed to be exposed to subsurface soil at depths from 0 to 5 feet, *via* incidental ingestion and dermal contact. The utility worker is assumed to have an exposure frequency of 10 days/year and an exposure duration of 10 years. The construction worker is assumed to have an exposure frequency of 50 days/year for 5 years.

3.1.2 Grassy Areas North, South, and East of Main Facility

The grassy and wooded areas located north, south, and east of the main facility encompass approximately the northern and southern thirds of the RMC property (Figure 1). The receptors evaluated in both of these areas include an adolescent trespasser and an adult groundskeeper under current use, and a future site worker. These receptors are assumed to be exposed to surface soil *via* incidental ingestion and dermal contact. The adolescent trespasser (age 13-18 years) is assumed to have an exposure frequency of 25 days/year and an exposure duration of 5 years. The groundskeeper is assumed to have an exposure frequency of 50 days/year and an exposure duration of 25 years. A future site worker is assumed to spend most of his time in the plant and surrounding paved areas. However, he may have occasion to visit the grassy/wooded areas for a walk or to eat lunch at a picnic table. The future site worker is assumed to have an exposure frequency in these areas of 4 days/week for 36 weeks/year or 144 days/year, and an exposure duration of 25 years.

3.1.3 Offsite Natural Gas Facility

At the offsite natural gas facility, an adult commercial worker was evaluated. The worker is assumed to be exposed to surface soil *via* incidental ingestion and dermal contact. The worker is assumed to have an exposure frequency in these areas of 5 days/week for 45 weeks/year, or 225 days/year, and an exposure duration of 25 years.

3.2 Exposure Point Concentrations

In a risk assessment, an Exposure Point Concentration (EPC) represents the concentration of a chemical in an environmental medium to which an individual is exposed. The calculation of EPCs is described below. The EPCs used in this risk evaluation are presented in Table 2.

Table 2
Exposure Point Concentrations

| | | | 1 | Arsenic | Lead | | |
|---------------------|--------------|--------|--------------|-----------------|--------------|-----------------|--|
| Exposure Area | Medium | Depth | EPC mg/kg | Basis 95%UCL | EPC mg/kg | Basis | |
| | Subsurface | | | | | | |
| Plant Area | Soil | 0-5 ft | 123 | NP, bootstrap | 20,266 | arithmetic mean | |
| Grassy Area | Surface Soil | 0-6 in | 312 | NP, bootstrap | 15,916 | arithmetic mean | |
| Offsite Natural Gas | | | | | | | |
| Facility | Surface Soil | 0-6 in | 28.5 | LN, H-UCL | 1,311 | arithmetic mean | |

NP Nonparametric

LN Lognormal

For arsenic, the EPCs were the 95% upper confidence level on the mean (95UCL) concentration. The 95UCL is used instead of the mean or arithmetic average because it is not possible to know the true mean (USEPA, 1992b). The 95UCL is defined as a value that ... "equals or exceeds the true mean 95% of the time" (USEPA, 1992b). As sampling data become more representative of actual site conditions, uncertainties decrease, and the 95UCL approaches the true mean. The 95UCL values were calculated with ProUCL© according to USEPA guidance (USEPA, 2002a).

To evaluate lead risks, the arithmetic mean soil lead concentration within the exposure area was used as the EPC to be consistent with USEPA guidance (USEPA, 1994; USEPA, 1996)

3.3 Quantification of Exposure

This section discusses the basis for calculating human intake levels resulting from exposures to COPCs other than lead (in this case arsenic), and describes each input parameter. Human intake levels for lead are discussed in Section 5. Exposure estimates represent the daily dose of a chemical taken into the body, averaged over the appropriate exposure period, expressed in the units of milligram (mg) of chemical per kilogram (kg) of human body weight per day. The primary source for the exposure equations used in the HHRA is the USEPA's "Risk Assessment Guidance for Superfund (RAGS)" (USEPA, 1989). The generalized equation for calculating chemical intakes is shown below:

$$I = \frac{EPC \times CR \times EF \times ED}{BW \times AT}$$

¹ Note that this approach is not used to evaluate lead. Consistent with USEPA guidance, lead exposure is evaluated using a child or adult lead model to estimate blood lead levels.

203030

where:

| I | = | Intake, the amount of chemical at the exchange boundary (mg/kg body weight-day), |
|-----|---|--|
| EPC | = | Exposure Point Concentration, the chemical concentration contacted over the exposure period at the exposure point (e.g., mg/kg in soil), |
| CR | _ | Contact Rate, the amount of contaminated medium contacted per unit time or |
| CK | _ | event (e.g., soil ingestion rate (mg/day)), |
| EF | = | Exposure Frequency, describes how often exposure occurs (days/year), |
| ED | = | Exposure Duration, describes how long exposure occurs (yr), |
| BW | = | Body Weight, the average body weight over the exposure period (kg), and |
| AT | = | Averaging Time, period over which exposure is averaged (days). |

Exposure factors (e.g., contact rate, exposure frequency, exposure duration, body weight) describe a receptor's exposure for a given exposure scenario. The values used for each exposure factor are summarized in Table 3 and discussed in detail below. The exposure factor input values are consistent with current USEPA guidance. Where appropriate, exposure parameters were based on site-specific considerations and professional judgment.

Table 3
Summary of Exposure Factor Input Values

| Exposure Area | Onsite Construction | Onsite | Grassy Area | Grassy Area Grounds- | Grassy Area Adolescent | Offsite Gas Facility |
|------------------------------------|------------------------|----------------|-------------|-------------------------|---------------------------|-------------------------|
| Receptor | Worker | Utility Worker | Site Worker | keeper | Trespasser | Worker |
| Exposure Pathway/Exposure Factor | | | | | | <u></u> |
| Ingestion of Soil | | | | | | |
| Ingestion Rate (mg/day) | 330 | 330 | 50 | 100 | 50 | 50 |
| Exposure Duration (yr) | 5 | 10 | 25 | 25 | 5 | 25 |
| Exposure Frequency (days/yr) | 50 | 10 | 144 | 50 | 25 | 225 |
| Body Weight (kg) | 70 | 70 | 70 | 70 | 58 | 70 |
| Bioavailability (arsenic) | 0.8 | 0.8 | 0.8 | 0.8 | 0.8 | 0.8 |
| Conversion Factor (kg/mg) | 0.000001 | 0.000001 | 0.000001 | 0.000001 | 0.000001 | 0.000001 |
| Fraction from Contaminated Source | 1 | 1 | 1 | 1 | 1 | 1 |
| Averaging Time (days) - Cancer | 25550 | 25550 | 25550 | 25550 | 25550 | 25550 |
| Averaging Time (days) - Non Cancer | 365 | 3650 | 9125 | 9125 | 1825 | 9125 |
| Dermal Contact with Soil | | | | | | |
| Dermal Absorption Factor (arsenic) | 0.03 | 0.03 | 0.03 | 0.03 | 0.03 | 0.03 |
| Soil Adherence Factor (mg/cm²) | 0.2 | 0.2 | 0.07 | 0.2 | 0.07 | 0.2 |
| Surface Area (cm ² /d) | 3300 | 3300 | 3300 | 3300 | 4270 | 3300 |
| Exposure Duration (years) | 5 | 10 | 25 | 25 | 5 | 25 |
| Exposure Frequency (days/yr) | 50 | 10 | 144 | 50 | 25 | 225 |
| Body Weight (kg) | 70 | 70 | 70 | 70 | 58 | 70 |
| Conversion Factor (kg/mg) | 0.000001 | 0.000001 | 100000.0 | 0.000001 | 0.000001 | 0.000001 |
| Fraction from Contaminated Source | 1 | 1 | 1 | 1 | 1 | 1 |
| Averaging Time (days) - Cancer | 25550 | 25550 | 25550 | 25550 | 25550 | 25550 |
| Averaging Time (days) - Non Cancer | 365 | 3650 | 9125 | 9125 | 1825 | 9125 |

3.3.1 Ingestion of Soil

For the soil ingestion pathway intake is calculated as:

$$Intake\left(\frac{mg}{kg \cdot day}\right) = \frac{C_{soil}\left(\frac{mg}{kg}\right) \times B \times IR_{soil}\left(\frac{mg}{day}\right) \times FS \times EF\left(\frac{days}{yr}\right) \times ED(yrs) \times 10^{-6} \frac{kg}{mg}}{BW(kg) \times AT(days)}$$

where:

 C_{soil} = Concentration of the chemical in soil (mg/kg)

B = Relative Bioavailability, the relative oral absorption fraction (unitless)

 IR_{soil} = Soil Ingestion Rate (mg/day)

FS = Fraction of Soil from the site (unitless)

EF = Exposure Frequency (days/year)

ED = Exposure Duration (years)

BW = Body Weight (kg)

AT = Averaging Time (days)

Gradient used conservative USEPA-recommended values for each of the input parameters. The basis for each value used is detailed below.

Soil Concentrations (C_{soil}). As summarized in Section 3.2, the 95UCL was used as the EPC.

Relative Bioavailability (B). To accurately quantify potential exposures from ingestion of soil, it is important to consider the amount of a chemical that is solubilized in gastrointestinal fluids and absorbed across the gastrointestinal tract into the bloodstream. A chemical present in soil may be absorbed less completely than the same dose of the chemical administered in toxicity studies used to evaluate safe dose levels. A relative bioavailability estimate for a specific compound represents the absorption fraction from soil (the exposure route of concern) relative to the absorption fraction from food or water (in most toxicity studies, chemical doses are administered in food or water).

It is widely recognized that bioavailability of many metals and organics from soil tends to be considerably lower than bioavailability from food or water. USEPA guidance recognizes the need to make adjustments for the reduced bioavailability of compounds in soil. Specifically, in Appendix A of USEPA's Risk Assessment Guidance for Superfund (USEPA, 1989, pg. A-3), USEPA notes:

If the medium of exposure in the site exposure assessment differs from the medium of exposure assumed by the toxicity value (e.g., RfD values usually are based on or have been adjusted to reflect exposure via drinking water, while the site medium of concern may be soil), an absorption adjustment may, on occasion, be appropriate. For example, a substance might be more completely absorbed following exposure to contaminated drinking water than following exposure to contaminated food or soil (e.g., if the substance does not desorb from soil in the gastrointestinal tract).

USEPA Region 10 risk assessment guidance provides default values for the bioavailability of arsenic in soil. Region 10 notes that if the site is a smelter site and its appears likely that the arsenic exists primarily as finely-grained oxides from smelter stack emissions, then a value of 80% relative bioavailability may be assumed. Region 10 notes that this value is supported by a conservative interpretation of the scientific literature (USEPA Region 10, 1997). A relative bioavailability of 80% was used for arsenic in this risk assessment.

For lead, the USEPA recommends an oral absorption factor for adults of 0.12 for ingestion of lead in soil, based on 20% absorption of soluble lead, and a relative bioavailability of 60% for lead in soil (i.e., $0.12 = 0.2 \times 0.6$) (USEPA, 1996). Gradient used the recommended USEPA absorption factor of 0.12 to evaluate ingestion of lead contaminated soil for adult receptors.

Soil Ingestion Rate (IR_{soil}). A daily soil and dust ingestion rate of 50 mg/day was used for the adolescent trespasser, site worker, and offsite gas facility worker. USEPA considers this value to be a reasonable central estimate of adult soil ingestion and notes that although this value is highly uncertain, "a recommendation for an upper percentile value would be inappropriate" (USEPA, 1997a). A daily soil and dust ingestion rate of 100 mg/day was used for the groundskeeper (USEPA, 2002b). A daily soil and dust ingestion rate of 330 mg/day was used for the onsite construction worker and the onsite utility worker, as these receptors are assumed to have more intensive contact with soil than the other adult receptors (USEPA, 2002b).

Fraction of Soil From the Site (FS). For all receptors, it was assumed that 100% of the individual's daily soil exposure occurred at the site. This assumption is likely to overestimate exposure to contaminated soil for workers and trespassers because workers are assumed to be at the site for only 8 hours per day, and trespassers are likely present less than 2 hours per visit.

Exposure Frequency (EF) and Exposure Duration (ED). The exposure frequency and duration used for each receptor are discussed in Section 3.1.1 to 3.1.3. For the site worker, groundskeeper, and offsite gas worker, the exposure duration is 25 years. This is the 95th percentile duration that an individual stays at any one workplace (USEPA, 1991). Hence, this assumption overestimates exposures for most workers, because the median occupational tenure of the working population has been estimated to be 6.6 years (USEPA, 1997a).

Body Weight (BW). Although the average U.S. adult body weight in the current Exposure Factors Handbook (USEPA, 1997a) is 71.8 kg, a mean adult body weight of 70 kg (USEPA, 1991) was used in the HHRA, so that the body weight would be consistent with that used in deriving the toxicity factors. Average body weight for the adolescent trespasser (13-18 year old) was calculated from data in USEPA's Exposure Factors Handbook and used in the HHRA (USEPA, 1997a).

Averaging Time (AT). For non-cancer risks, the averaging time was equal to the exposure duration multiplied by 365 days/year. For cancer risks, exposures were averaged over a 70-year average lifetime (USEPA, 1991). Although the current life expectancy for men and women in the U.S. is 76.7 years (USEPA, 1997a), a value of 70 years (25,550 days) was used to be consistent with the value used in deriving the toxicity factors.

3.3.2 Dermal Contact with Surface Soil

For dermal exposure to contaminants in soil, a dermal intake (the amount absorbed into the body) is calculated as (USEPA, 2004c):

$$Intake \left(\frac{mg}{kg \cdot day}\right) = \frac{C_{soil}\left(\frac{mg}{kg}\right) \times DA \times AF\left(\frac{mg}{cm^{2}}\right) \times SA\left(\frac{cm^{2}}{event}\right) \times EF\left(\frac{events}{yr}\right) \times ED(yrs) \times 10^{-6} \frac{kg}{mg}}{BW(kg) \times AT(days)}$$

where:

```
C_{soil} = Concentration of the chemical in soil (mg/kg),
```

DA = Dermal Absorption factor (unitless)
AF = Soil/skin Adherence Factor (mg/cm²),

SA = Skin surface Area exposed (cm²/exposure event),

EF = Exposure Frequency (exposure events/year),

ED = Exposure Duration (years), BW = Body Weight (kg), and

AT = Averaging Time (days).

There are three parameters in this equation that are different from those discussed in the previous section (Section 3.3.1). Only those parameters unique to the dermal exposure equation, dermal absorption fraction (DA), the soil adherence factor (AF), and the skin surface area (SA), are discussed in this section.

Note that since absorbed doses are used for the dermal pathway, the toxicity criteria are adjusted so they apply to absorbed doses. This adjustment is discussed in more detail in the toxicity section (Section 4).

Dermal Absorption Fraction (DA). The dermal absorption fraction represents the amount of a chemical in contact with skin that is absorbed through the skin and into the bloodstream. The dermal absorption fraction for arsenic (0.03) was obtained from USEPA's dermal risk assessment guidance (USEPA, 2004c; Table 3.4).

Soil to Skin Adherence Factor (AF). The adherence factor relates the amount of soil that adheres to the skin per unit of surface area (USEPA, 2004c). Adherence factors vary depending on the properties of the soil, the part of the body, and the type of activity. Gradient used the 50th percentile weighted adherence factors from USEPA's dermal risk assessment guidance (USEPA, 2004c). The AF for utility workers (0.2 mg/cm²) was used for the construction worker, utility worker, groundskeeper, and offsite gas facility worker. EPA's recommended AF for the residential adult (0.07 mg/cm²) was used for the future site worker and the adolescent trespasser.

Skin Surface Area Exposed (SA). This parameter reflects the amount of skin that is available for exposure to soil. The skin surface areas used in the HHRA were 3300 cm² for the construction worker, utility worker, site worker, groundskeeper, and offsite gas facility worker, based on the face, hands, and

forearms; and 4270 cm² for the trespasser, based on the face, hands, forearms, and lower legs. Surface areas were calculated using USEPA's Exposure Factors Handbook (USEPA, 1997a).

4 Toxicity Assessment

4.1 Overview of Toxicity Values

Gradient has evaluated potential cancer and non-cancer risks from exposure to arsenic using dose-response relationships for carcinogenicity (oral Cancer Slope Factors) and systemic toxicity (oral Reference Doses). Lead toxicity is discussed separately in Section 4.2. The primary source of toxicity values was the USEPA's Integrated Risk Information System (IRIS) (USEPA, 2004a). Toxicity values in IRIS undergo a rigorous peer review process and are generally considered to be of high quality. The toxicity factors used in the HHRA are summarized in Table 4-1.

Table 4
Toxicity Factors

| Compound | RfD _{oral} (mg/kg- day) | Critical Effect | RfD Source | Uncertainty Factor | Oral Absorption | RfD _{dermal} (mg/kg- day) | CSF _{oral} (mg/kg- day) | CSF _{dermal} (mg/kg- day) |
|----------|--|---|---------------|-----------------------|--------------------|--|--|--|
| Arsenic | 0.0003 | Hyperpigmentation, keratosis and possible vascular complications | IRIS | 3 | 95% | 0.0003 | 1.5 | 1.5 |

4.1.1 Oral Reference Doses (RfD_{oral})

An RfD is an estimate of daily exposure that a sensitive population can experience over a lifetime with a negligible risk of systemic health effects. The USEPA derives RfDs by first identifying the highest dose level that does not cause observable adverse effects (*i.e.*, the No Observed-Adverse Effect Level, or NOAEL; USEPA, 1993). If a NOAEL was not identified, a Lowest Observed Adverse Effect-Level, or LOAEL, may be used. This dose level is then divided by uncertainty factors to calculate an RfD. An uncertainty factor of 100 is often used, to account for interspecies differences (if animal studies were used) and sensitive human subpopulations (*e.g.*, children and the elderly; USEPA, 1993). Additional uncertainty factors may be used, depending on the quality of the toxicological data.

4.1.2 Oral Cancer Slope Factors (CSF_{oral})

The CSF is an upper bound estimate of carcinogenic potency used to calculate risk from exposure to carcinogens, by relating estimates of lifetime average chemical intake to the incremental risk

of an individual developing cancer over their lifetime (USEPA, 1992c). The CSFs recommended by the USEPA are conservative upper bound estimates, which means that the USEPA is reasonably confident that the "true" cancer risk does not exceed the estimated risk calculated using the CSF, and may be as low as zero.

4.1.3 Dermal Reference Doses (RfD_{dermal})

There are no USEPA-derived toxicity values based specifically on toxicity studies involving dermal exposures. In the absence of dermal-specific RfDs, oral toxicity factors are used, assuming that once a chemical is absorbed into the blood stream, the health effects are similar regardless of whether the route of exposure is oral or dermal. However, since oral toxicity criteria are based on the amount of a chemical *administered* per unit time and body weight (chemical intake), they need to be adjusted to be applicable to *absorbed* doses (dermal exposures are expressed as absorbed intake levels) (USEPA, 1989; 1992a; 2004c).

Since most RfDs are based on studies where a chemical is administered in food or water, this adjustment is made using the oral absorption efficiency for that chemical. If oral absorption is very high (almost 100%), then the absorbed dose is virtually the same as the administered dose, and no adjustment of the toxicity factor is necessary. If oral absorption is very low (e.g., 5%), the absorbed dose is much smaller than the administered dose, and an adjustment of the toxicity criteria is necessary. For any given chemical, the USEPA recommends adjusting the oral toxicity factor for use in evaluating dermal risks only when the oral absorption for that chemical is less than 50%, to "obviate the need to make comparatively small adjustments in the toxicity value that would otherwise impart on the process a level of accuracy that is not supported by the scientific literature" (USEPA, 2004c).

For non-cancer effects, this adjustment is made by multiplying the oral RfD (for applied doses) by the oral absorption efficiency (i.e., $RfD_{oral} \times Abs_{oral} = RfD_{dermal}$). For arsenic, the oral absorption efficiency is 95%, therefore no adjustment is necessary and the RfD_{dermal} is the same as the RfD_{oral} (Table 4).

4.1.4 Dermal Cancer Slope Factors (CSF_{dermal})

There are no USEPA-derived toxicity values specifically for cancer studies involving dermal exposures. In the absence of dermal-specific CSFs, oral CSFs are used, assuming that once a chemical is

absorbed into the blood stream, the carcinogenic effect is similar regardless of whether the route of exposure is oral or dermal. However, since oral CSFs are based on the amount of a chemical administered per unit time and body weight (chemical intake), they need to be adjusted to be applicable to absorbed doses (dermal exposures are expressed as absorbed intake levels) (USEPA, 1989; 1992a; 2004c). For any given chemical, the USEPA recommends adjusting the oral CSF for use in evaluating dermal risks only when the oral absorption for that chemical is less than 50%, to "obviate the need to make comparatively small adjustments in the toxicity value that would otherwise impart on the process a level of accuracy that is not supported by the scientific literature" (USEPA, 2004c).

For cancer, this adjustment is made by dividing the oral CSF (for applied doses) by the oral absorption efficiency (i.e., CSF_{oral} / $Abs_{oral} = CSF_{dermal}$), if the oral absorption efficiency is less than 50%. For arsenic, this value is 95%, therefore the CSF_{dermal} is the same as the CSF_{oral} (Table 4).

4.2 Toxicity Values for COPCs

The basis of the arsenic toxicity values is described in this section and summarized in Table 4. Lead toxicity is also discussed in this section because of the unique way exposure and risk are evaluated for this metal.

4.2.1 Arsenic

The toxicity criteria for arsenic were obtained from the USEPA IRIS database (USEPA, 2004a). The derivation of each of these values, and the scientific uncertainties concerning arsenic toxicity, are discussed below.

4.2.1.1 Arsenic RfD_{oral}

USEPA cites an RfD_{oral} for arsenic of 0.0003 mg/kg-day (USEPA, 2004a). The arsenic RfD_{oral} is based on increased incidence of hyperpigmentation, keratosis and possible vascular complications in a study of a large population (over 40,000 people) in Taiwan with chronic exposure to arsenic in drinking water and food (Tseng, 1977; Tseng *et al.*, 1968). The USEPA characterized a NOAEL of 0.0008 mg/kg/day for skin lesions in the Tseng study, based on the drinking water concentration in the NOAEL group (0.009 mg/L), an assumed drinking water ingestion rate of 4.5 L, daily arsenic intake from sweet potatoes and rice of 0.002 mg/day, and an average Taiwanese body weight of 55 kg ((0.009 mg/L \times 4.5

L/day) + 0.002 mg/day / 55 kg) (Abernathy et al., 1989). An uncertainty factor of 3 (based on the lack of reproductive toxicity data and uncertainty regarding toxicity in sensitive individuals) was applied to the NOAEL to derive an RfD of 0.0003 mg/kg/day (0.0008/3). Overall, the USEPA has "medium" confidence in the study, "medium" confidence in the database (due to poor characterization of the dose levels in the Tseng and other supporting studies), and "medium" confidence in the RfD_{oral} for arsenic. It is noted in the arsenic IRIS file that a clear consensus does not exist among USEPA scientists regarding arsenic systemic toxicity (USEPA, 2004a).

4.2.1.2 Arsenic CSF_{oral}

USEPA concluded that arsenic is a "human carcinogen," a weight-of-evidence classification for carcinogenicity of "A" (USEPA, 2004a). This classification is based on sufficient evidence of carcinogenicity in human populations. Lung cancer has been associated with inhalation of arsenic, and skin, bladder, and possibly other internal cancers have been associated with ingestion of arsenic in drinking water.

In IRIS, the USEPA recommends a CSF_{oral} value for arsenic of 1.5 (mg/kg/day)⁻¹ (USEPA, 2004a). This value is based on skin cancer incidence rates in the same Taiwanese study used as the basis for the RfD_{oral} value (Tseng, 1977; Tseng *et al.*, 1968). This value was calculated using a multistage model, assuming a drinking water ingestion rate of 3.5 L/day for Taiwanese males and 2 L/day for Taiwanese females, an average Taiwanese body weight of 55 kg, and an average U.S. body weight of 70 kg.

There is currently considerable debate among the scientific community regarding the arsenic CSF_{oral}. Many researchers believe that the current value of 1.5 (mg/kg/day)⁻¹ may overestimate cancer risks for U.S. populations (see, for example, Slayton *et al.*, 1996; Chappell *et al.*, 1997).

4.2.1.3 Arsenic RfD_{derm} and CSF_{derm}

In general, for dermal exposures (expressed as absorbed intake levels), the RfD_{oral} and CSF_{oral} are adjusted to be applicable to absorbed doses (USEPA, 1989; 1992a). This adjustment is made assuming that once a chemical is absorbed into the blood stream, the health effects are similar regardless of whether the route of exposure is oral or dermal. However, since oral absorption for arsenic is about 95%

(USEPA, 2004c), and the USEPA recommends adjusting dermal toxicity factors only when oral absorption is less than 50%, no adjustment was made for arsenic.

4.2.2 Lead

The ingestion of lead at certain levels can result in significant health effects, particularly among children. Epidemiological investigators have reported a correlation between blood lead levels (BLLs) in children and adverse health effects. High levels of lead intake can cause kidney damage, convulsions, coma, and even death (ATSDR, 1999). However, health effects resulting from lower levels of lead exposure are more common, and are related to cognitive and neuro-behavior impacts, including the impairment of intellectual performance.

The USEPA has not established any toxicity criteria (RfD, CSF) for lead (USEPA, 2004b); instead, lead risks are evaluated by modeling blood lead levels. Lead risks in adults were evaluated using USEPA's Adult Lead Model (USEPA, 2003). This model is discussed in more detail in Section 5.4.

The USEPA has assigned lead a Weight-of-Evidence Classification for human carcinogenicity of "B2", a "probable human carcinogen," based on sufficient animal evidence but inadequate human evidence (USEPA, 2004b). Even though the weight of evidence for lead carcinogenicity is B2, the USEPA does not evaluate lead cancer risk using a CSF, having concluded that neurological effects in young children are the most relevant endpoint.

5 Risk Characterization

In this section, cancer and non-cancer health risks are estimated by combining the information from Sections 2 through 4. The calculations used to estimate cancer and noncancer risks are presented in Sections 5.1 and 5.2, respectively. Section 5.3 discusses the calculated cancer and noncancer risks for each exposure area. Section 5.4 presents the lead risks by exposure area. Section 5.5 provides a qualitative discussion of the most significant sources of uncertainty in the risk estimates.

5.1 Calculation of Cancer Risks

Excess lifetime cancer risks are characterized as the incremental probability that an individual will develop cancer during his or her lifetime due to chemical exposure to constituents at the site under the specific exposure scenarios evaluated. The term "incremental" implies the risk above the background cancer risk experienced by all individuals in the course of daily life. According to Greenlee *et al.* (2001), the lifetime probability of developing cancer (*i.e.*, background cancer risk) is approximately 0.435 in men, and 0.383 in women. Cancer risks are expressed as a unitless probability (*e.g.*, one in a million, or 10^{-6}) of an individual developing cancer over a lifetime, above background risk, as a result of exposure to impacted environmental media at a site.

Excess (incremental) cancer risks for all of the exposure pathways (oral, dermal, and inhalation) are calculated using intake estimates (lifetime average daily doses, calculated in Section 3 as part of the exposure assessment) and CSFs (summarized as part of the toxicity assessment in Section 4) as follows (USEPA, 1989):

$$CancerRisk = Intake \left(\frac{mg}{kg \cdot day}\right) \times CSF \left(\frac{mg}{kg \cdot day}\right)^{-1}$$

For ingestion pathways, oral intake estimates (expressed as applied or administered dose levels) are multiplied by the oral CSF (applicable to applied/administered doses). Similarly, for inhalation pathways, inhalation intake estimates (also expressed as applied or administered dose levels) are multiplied by the inhalation CSF (applicable to applied/administered doses). For dermal exposures, dermal intake estimates (expressed as an absorbed dose level) are multiplied by an adjusted oral CSF (adjusted to apply to absorbed doses) (USEPA, 2004c). The total cancer risk for each receptor is the sum of the risks across all of the exposure pathways.

5.2 Calculation of Noncancer Risks

Risks from non-carcinogenic health effects are expressed as hazard quotients rather than as probabilities. A hazard quotient compares the calculated exposure (average daily doses, calculated as part of the exposure assessment in Section 3) to acceptable reference exposures derived by the USEPA (e.g., RfDs, summarized as part of the toxicity assessment in Section 4). The hazard quotient is calculated from the RfD as follows (USEPA, 1989):

$$HazardQuotient = \frac{Intake \left(\frac{mg}{kg \cdot day}\right)}{RfD \left(\frac{mg}{kg \cdot day}\right)}$$

For the ingestion exposure route an oral intake estimate (expressed as applied or administered dose) is divided by the oral RfD (applicable to applied/administered dose). Similarly, for the inhalation exposure route an inhalation intake estimate (also expressed as applied or administered dose) is divided by the inhalation RfD (applicable to applied/administered dose). For dermal exposure, a dermal intake estimate (expressed as an absorbed dose) is divided by an adjusted oral RfD (adjusted to apply to absorbed dose).

Hazard indices are calculated for each receptor and exposure pathway, according to USEPA guidance (1989). A hazard index greater than 1.0 is considered to represent a significant health risk. Because a hazard quotient is simply a ratio of site exposures to reference exposure levels (e.g., RfDs, RfCs, etc.), hazard indices do not represent the probability that an adverse health effect could occur. They simply indicate whether an estimated exposure for an individual presents a significant noncancer health risk, based on the USEPA's recommended reference dose.

5.3 Estimated Cancer and Noncancer Risks

The estimated cancer and noncancer risks for arsenic are discussed below by exposure area. Lead risks are discussed separately in Section 5.4. Cancer risks are summarized in Table 5. The total cancer risk for each receptor is the sum of the risks over all exposure routes and all exposure periods. Noncancer risks are summarized in Table 5. The total noncancer risk for each receptor is the sum of the

20

203030 ro0404t.doc risks over all exposure routes. The detailed risk calculation tables in Appendix A present the arsenic risks calculated for each receptor and exposure pathway. The percent contribution of each exposure pathway to the total risk is also shown.

5.3.1 Main Facility Area

In the main facility area onsite, we evaluated a construction worker and a utility worker for exposure to arsenic in subsurface soil *via* incidental ingestion and dermal contact.

The total excess lifetime cancer risk is 7×10^{-6} for the construction worker, and 3×10^{-6} for the utility worker. These risk estimates are within USEPA's target risk range of 1×10^{-6} to 1×10^{-4} .

The total hazard index (HI) is 0.2 for the construction worker, and 0.05 for the utility worker. These values are well below a HI of 1.0.

5.3.2 Grassy Areas

In the grassy areas located north, south, and east of the main facility, we evaluated a future site worker, a groundskeeper, and an adolescent trespasser, for exposure to arsenic in surface soil *via* incidental ingestion and dermal contact.

The total excess lifetime cancer risks are 4×10^{-5} for the future site worker, 3×10^{-5} for the groundskeeper, and 2×10^{-6} for the adolescent trespasser. These risk estimates are within USEPA's target risk range of 1×10^{-6} to 1×10^{-6} .

The total hazard index (HI) is 0.3 for the future site worker, and 0.2 for the groundskeeper, and 0.06 for the adolescent trespasser. These values are well below a HI of 1.0.

5.3.3 Offsite Natural Gas Facility

At the off-site natural gas facility to the west of the RMC property, we evaluated a facility worker exposed to arsenic in surface soil *via* ingestion and dermal contact.

The total excess lifetime cancer risk is 8×10^{-6} for the gas facility worker. This risk estimate is within USEPA's target risk range of 1×10^{-6} to 1×10^{-4} .

The total hazard index (HI) is 0.05 for the gas facility worker. This value is well below a HI of 1.0.

Table 5
Summary of Cancer and Noncancer Risks

| Exposure Area | Medium | Receptor | Total Excess Lifetime Cancer Risk | Total Hazard Index |
|----------------------------------|-----------------|-----------------------|---|-----------------------|
| Main Plant Area | Subsurface soil | Construction Worker | 7E-06 | 0.2 |
| Iviani Fiant Atea | Substitute soil | Utility Worker | 3E-06 | 0.05 |
| | | Groundskeeper | 3E-05 | 0.2 |
| Grassy Areas | Surface soil | Adolescent Trespasser | 2E-06 | 0.06 |
| | | Future Site Worker | 4E-05 | 0.3 |
| Off Site Natural Gas Facility | Surface soil | Adult Worker | 8E-06 | 0.05 |

5.4 Lead Risk Assessment

5.4.1 Adult Lead Model

Blood lead levels (BLLs) in adolescents and adults are assessed using USEPA's Adult Lead Model (ALM) (USEPA, 1996). USEPA's Adult Blood Lead Model predicts a median BLL estimate for an adult as a function of the baseline BLL plus an increment that is attributable to exposure to site soil. This increment is a function of the biokinetic slope factor, the concentration of lead in soil, the soil ingestion rate, the fraction of lead in soil that is absorbed, and the exposure frequency. EPA has selected a target BLL for an adult female, in order to protect a developing fetus such that no more than 5% of fetuses would be expected to have BLLs exceeding $10 \mu g/dL$.

The basic form of the equation for the ALM is as follows:

$$BLL_{adult} = PbB + \frac{\left(EF \times AF \times PbS \times IR \times BKSF\right)}{AT}$$

The input values used in the model are summarized in Table 6 and described below. First, an average baseline lead concentration in blood (PbB_{base}) for adults is identified to account for continuing 203030

exposure to background levels of lead in food, soil, and dust, and pre-existing body burdens due to prior lead exposures. Baseline BLLs were obtained from the most recent National Health and Nutrition Examination Survey, from 1999-2000 (NHANES, 2000) (U.S. Public Health Service, 2004). For adults we used the geometric mean (GM) and geometric standard deviation (GSD) BLLs for women of childbearing age (age 20-49). For the adolescent trespasser, we used the GM and GSD BLLs for males and females combined, for 13-18 year olds. To this baseline, the model adds the incremental increase in blood lead due to the lead source of interest (in this case, exposure to lead *via* ingestion of soil and dust).

The concentration of lead in soil (PbS) is the mean lead concentration in each exposure area. Lead uptake is calculated by multiplying the concentration of lead in soil by the soil/dust ingestion rate (IR) and the absorption fraction (AF) for lead in soil and dust. The AF is the amount of lead that is absorbed into the bloodstream from the gastrointestinal tract. The exposure frequency (EF) varies by receptor and exposure area. The EFs used for each receptor are presented in Table 3. The averaging time (AT) for chronic exposure to lead in soil is assumed to be one year (*i.e.*, 365 days). The biokinetic slope factor (BKSF) relates the incremental lead uptake into the body to an incremental increase in blood lead level in adults. USEPA's default value of 0.4 was used for the BKSF.

Table 6
Adult Lead Model Input Values

| Term | Definition | Value |
|------------------|--|--------------------------------|
| PbB ₀ | Geomean baseline BLL (µg/dL) for Adult females | |
| | (age 20-49 yr) | 1.2 |
| GSD | Geometric standard deviation for Adult females | 1.8 |
| PbB_0 | Geomean baseline BLL ($\mu g/dL$) for 13-18 yr old males and females | 1.1 |
| GSD | Geometric standard deviation for 13-18 yr old males and females | 1.8 |
| EF | Exposure Frequency (i.e., number of days during the averaging time an individual is exposed to the lead source being evaluated (days)) | Receptor-specific |
| AT | Averaging Time (days) | 365 |
| PbS | Soil/dust lead concentration (μg/g) | Area-Specific |
| IR | Soil/dust Ingestion Rate (g/day) | Receptor-specific 0.05 or 0.10 |
| AF | Fraction of ingested lead absorbed into the blood stream (dimensionless) | 0.12 |
| BKSF | Biokinetic Slope Factor (change in blood lead per μ g change in daily lead uptake) (μ g/dL per μ g/day) | 0.4 |

Total BLLs for adults are predicted by adding the estimated incremental increase in blood lead to the average baseline BLL. A geometric standard deviation (GSD) appropriate for adults is used to estimate the probable range of BLLs around the predicted geometric mean adult BLL from the model. For this evaluation, we used the actual GSDs for the BLLs obtained from the NHANES-2000 database.

BLLs estimated using the ALM are evaluated based on a comparison to the USEPA risk management criterion for lead. Specifically, the health protection goal of the USEPA Office of Solid Waste and Emergency Response is to "limit exposure to soil lead levels such that a typical (or hypothetical) child or group of similarly exposed children would have an estimated risk of no more than 5% of exceeding a blood lead of 10 μ g/dL" (USEPA, 1998). The Centers for Disease Control (CDC) recommend that "the goal of all lead poisoning prevention activities should be to reduce children's BLLs below 10 μ g/dL" (CDC, 1991). Based on a goal of keeping the BLL in children at or below 10 μ g/dL, the BLL for women of child-bearing age should not exceed 11.1 μ g/dL, because the fetal BLL is approximately 90% of the maternal BLL (*i.e.*, 90% of 11.1 μ g/dL is 10 μ g/dL). A BLL goal of 10 μ g/dL was used for the adolescent trespasser.

The adult lead modeling results for all receptors, along with the input values, the predicted BLLs, and the probability of exceeding the target BLL, are presented in Table 7. The adult lead modeling results are discussed below by exposure area. The dermal exposure route for lead in soil was not evaluated because this exposure route is typically insignificant when compared to ingestion. The ALM makes no provision for assessing dermal exposures.

Table 7
Summary of Lead Risks and Cleanup Goals

| | Soil E | xposure Depth | 0-5 ft | 0-5 ft | 0-6" | 0-6" | 0-6" | 0-6" |
|-----------------------------|--|---------------------|--------------|----------------|----------------|-------------------|--------|-------------------------|
| | | | | Values for | r Non-Resident | tial Exposure Sco | enario | |
| Exposure | | | Or | site | | Grassy Area | | Offsite Gas Facility |
| | | | Construction | Ĭ i | Grounds- | | | |
| Variable | Description of Exposure Variable | Units | Worker | Utility Worker | keeper | Trespasser | Worker | Worker |
| PbS | Soil lead concentration | ug/g or ppm | 20,266 | 20,266 | 15,916 | 15,916 | 15,916 | 1311 |
| R _{fetal/maternal} | Fetal/maternal PbB ratio | | 0.9 | 0.9 | 0.9 | 0.9 | 0.9 | 0.9 |
| BKSF | Biokinetic Slope Factor | ug/dL per ug/day | 0.4 | 0.4 | 0.4 | 0.4 | 0.4 | 0.4 |
| GSD _i | Geometric standard deviation PbB | | 1.8 | 1.8 | 1.8 | 1.8 | 1.8 | 1.8 |
| PbB ₀ | Baseline PbB | ug/dL | 1.2 | 1.2 | 1.2 | 1.1 | 1.2 | 1.2 |
| IR_S | Soil ingestion rate (including soil-derived indoor dust) | g/day | 0.100 | 0.100 | 0.050 | 0.050 | 0.050 | 0.050 |
| IR _{S+D} | Total ingestion rate of outdoor soil and indoor dust | g/day | | | | | | |
| Ws | Weighting factor; fraction of IR _{S+D} ingested as outdoor soil | | | | | 1 | | |
| K _{SD} | Mass fraction of soil in dust | | | | | | | |
| AF _{S, D} | Absorption fraction (same for soil and dust) | | 0.12 | 0.12 | 0.12 | 0.12 | 0.12 | 0.12 |
| EF _{S, D} | Exposure frequency (same for soil and dust) | days/yr | 50 | 10 | 50 | 25 | 144 | 225 |
| AT _{S, D} | Averaging time (same for soil and dust) | days/yr | 365 | 365 | 365 | 365 | 365 | 365 |
| PbB _{adult} | PbB of adult worker, geometric mean | ug/dL | 15 | 3.9 | 6.4 | 3.7 | 16 | 3.1 |
| PbB _{fetal, 0.95} | 95th percentile PbB among fetuses of adult workers | ug/dL | 34 | 9.1 | 15 | 8.8 | 39 | 7.4 |
| PbB _t | Target PbB level of concern (e.g., 10 ug/dL) | ug/dL | 10.0 | 10.0 | 10.0 | 10.0 | 10.0 | 10.0 |
| $P(PbB_{fetal} > PbB_t)$ | Probability that fetal PbB > PbB, assuming lognormal distri | % | 68% | 4% | 18% | 3% | 74% | 2% |
| PRG | Preliminary Remediation Goal (PRG) | ppm | 4601 | 23003 | 9201 | 19011 | 3195 | 2045 |
| | Clean Fill (assumed) | ppm | 50 | | | | 50 | |

Source: U.S. EPA (1996). Recommendations of the Technical Review Workgroup for Lead for an Interim Approach to Assessing Risks Associated with Adult Exposures to Lead in Soil

5.4.2 Main Facility Area

In the main facility area, lead risks were evaluated for a construction worker and a utility worker exposed to subsurface soil (0-5 ft). The predicted 95th percentile fetal BLLs are 34 μ g/dL for the construction worker and 9.1 μ g/dL for the utility worker. The predicted BLL for the fetus of the construction worker exceeds the BLL goal of 10 μ g/dL, thus lead in subsurface soil poses an unacceptable risk in the main facility area. The exceedance is due to the elevated subsurface soil EPC of 20,266 mg/kg, which represents the average concentration for depths of 0-5 ft across the site. The utility worker has a much lower exposure frequency than the construction worker, thus his predicted 95th percentile BLL is below the adult 95th percentile goal of 10 μ g/dL.

5.4.3 Grassy Areas

In the grassy area, lead risks were evaluated for a future site worker, a groundskeeper, and an adolescent trespasser exposed to surface soil. The predicted 95th percentile fetal BLLs are 15 μ g/dL for the groundskeeper, 8.8 μ g/dL for the trespasser, and 39 μ g/dL for the future site worker. The predicted fetal BLLs for the groundskeeper and the future site worker exceed the BLL goal of 10 μ g/dL, thus lead in surface soil poses an unacceptable risk in this exposure area. This exceedance is due to the elevated surface soil lead concentration in the grassy area (15,916 mg/kg).

5.4.4 Offsite Natural Gas Facility

At the offsite natural gas facility, lead risks were evaluated for an offsite worker exposed to surface soil. The predicted 95th percentile fetal BLL is 7.4 μ g/dL for the offsite worker. The predicted BLL is below the goal of 10 μ g/dL, therefore, lead does not pose a significant risk to a worker exposed to surface soil in this exposure area.

5.5 Uncertainty Analysis

The process of evaluating human health risks involves multiple steps. Inherent in each step of the process are uncertainties that ultimately affect the final risk estimates. Uncertainties may exist in numerous areas, including sample collection, laboratory analysis, derivation of toxicity values, and estimation of potential site exposures. These uncertainties may result in either an over- or underestimation of risks. However, for this risk assessment, where uncertainties existed, Gradient took a

conservative approach in regards to parameters, assumptions, and methodologies, so as to overestimate potential exposures and risks. The most important contributors to uncertainty in this risk assessment are discussed below.

5.5.1 Uncertainties in Exposure Assessment

Soil Ingestion Rate. The adult soil ingestion rate used in the risk calculations and in the ALM was the USEPA default value of 0.05 g/day. However, a survey of recent literature suggests that the average soil and dust ingestion rate value for adults is closer to 0.02 g/day (Bowers et al., 1994).

Lead Absorption Fraction. A lead absorption fraction used in the ALM was USEPA's default value of 0.12. This value is based on 20% absorption of lead from water, and 60% relative bioavailability of lead from soil (0.20 x 0.60 = 0.12). The 20% absorption of lead from water is an upper-end value based on consumption on an empty stomach. This is a conservative assumption that may overestimate risk. O'Flaherty (1993) suggests that a value of 8% may be a more appropriate absorption value for food and water in adults. This value assumes that people consume food at average mealtimes throughout the day, therefore the lead absorption rate is slower due to the presence of food in the stomach. If we use an adult soil ingestion rate of 0.02 g/day, combined with a lead absorption fraction of 8% (or for soil, $0.08 \times 0.6 = 0.048$), we find that the lead risks calculated for adult receptors could be on the order of 60-70% lower than those presented here. Thus the adult lead risks presented in this report are likely conservative overestimates.

Fraction from site. Each receptor's daily soil exposure was assumed to be solely from impacted soil within the exposure area. This is a conservative assumption, since it is expected that workers would be at the site for only 8 hours a day, and would be exposed to soil and dust from other sources during the remaining part of each day (e.g., from home). For instance, in the grassy area, the exposure is likely overestimated for the future site worker, since we assumed he would obtain 100% of this daily soil ingestion during the hour or so that he visits the grassy area at lunchtime.

Exposure Duration. Gradient assumed an upper bound (95th percentile) exposure duration of 25 years for the future site worker, groundskeeper, and offsite gas facility worker (USEPA, 1991). This assumption is conservative and is likely to result in an overestimate of exposure and risk for most workers, since many workers do not remain at the same job for 25 years.

5.5.2 Uncertainties in Arsenic Risk Assessment

Risk management decisions for arsenic are confounded by the unusual nature of natural arsenic background risks, which for both food and water yield cancer risks of 10⁻⁴ or higher, and because of the substantial uncertainty associated with the arsenic cancer slope factor. This section describes some of the unique uncertainties associated with arsenic. In general, the assumptions we have used tend to overestimate arsenic risks.

5.5.2.1 Background Levels of Arsenic in Food, Water, Air, and Soil

Humans are exposed to low levels of arsenic in food, water, air, and soil (ATSDR, 2000). Food is typically the largest source of arsenic exposure, with dietary exposure accounting for about 70% of the daily intake of inorganic arsenic (Borum and Abernathy, 1994). The U.S. EPA estimates that the U.S. population ingests approximately 18 μ g of inorganic arsenic every day from food (USEPA 1988). This translates into a $4x10^{-4}$ cancer risk estimate based on continuous lifetime exposure, and EPA's current assessment of the carcinogenic potential of arsenic.

In the U.S., the average background level of arsenic in drinking water is approximately 2 μg/L (ATSDR, 2000). The recent U.S. EPA rule allows a permissible level or maximum contaminant level (MCL) of 10 μg/L arsenic in drinking water (USEPA, 2001a), a 5-fold lower value than the prior MCL of 50 μg/L. The rule allows community and non-transient, non-community water systems 5 years to attain compliance with the new MCL. Assuming the average background level and an ingestion rate of 2 L drinking water per day, an adult would ingest 4 μg inorganic arsenic per day. At the new MCL of 10 μg/L, an adult would ingest 20 μg inorganic arsenic per day, while at the old MCL of 50 μg/L, an adult would ingest 100 μg inorganic arsenic per day. These values translate into a range of cancer risk estimates between 9x10⁻⁵ and 2x10⁻³ based on continuous lifetime exposure, and EPA's current assessment of the carcinogenic potential of arsenic. EPA currently estimates that approximately 11 million people in the U.S. are served by community water systems with arsenic levels above the revised MCL. These people therefore have a cancer risk from water alone above 4x10⁻⁴.

The mean levels of arsenic in ambient air range from less than 1 to 3 ng/m³ in rural areas and from 20 to 30 ng/m³ in urban areas (ATSDR, 2000). Assuming an inhalation rate of 20 m³/day, an adult

would breathe in less than 0.02 to 0.06 μ g inorganic arsenic per day in rural areas, and 0.4 to 0.6 μ g in urban areas. Arsenic levels could be higher in urban areas due to emissions from coal-fired power plants. However, the maximum concentrations measured in a 24-hour period are generally below 100 ng/m³ (ATSDR, 2000). These background values translate into a range of cancer risk estimates between 4×10^{-7} and 1×10^{-5} .

Background arsenic levels in soil in Indiana range from 3.6 to 15 mg/kg, with an average concentration of 7.5 mg/kg (Dragun and Chiasson, 1991).

Total cancer risk from a combination of background exposures to arsenic in food, water, air, and soil may be as high as between 10^{-4} and 10^{-3} for a substantial portion of the U.S. population.

5.5.2.2 Body Burdens of Arsenic

Soil arsenic has a modest impact on body burden, as evidenced by urinary arsenic levels. Although elevated urinary arsenic levels were reported to be associated with very high soil arsenic levels near copper smelters (Baker *et al.*, 1977; Binder *et al.*, 1987), several studies consistently demonstrated that very low urinary arsenic levels were produced from soil arsenic concentrations below 200 mg/kg. In addition, the Anaconda, MT study demonstrated that urinary arsenic levels were unaffected by soil arsenic levels as high as 500 mg/kg. This observation occurs in part because of the small impact of soil arsenic relative to the impact of background levels of arsenic in food and water.

5.5.2.3 Bioavailability of Arsenic in Soil

Another explanation for the minor impact of soil arsenic on body burdens of arsenic is that arsenic in soil has a relatively low bioavailability and is absorbed into the body (i.e., bloodstream) less efficiently than arsenic in water, the form used by U.S. EPA for the arsenic cancer slope factor. The bioavailability of arsenic in soil depends on two steps: solubilization in gastrointestinal (GI) fluids and absorption across the GI epithelium into the bloodstream (Valberg et al., 1997). Both the solubilization and absorption depend on a variety of factors including the chemical forms of arsenic, the mode of intake by the individual (with or without food, type of food), and the nutritional status, which affects the pH throughout the GI tract, and GI transit time.

The solubility of arsenic depends on soil particle size and the associated soil matrix materials. Particle size affects solubility because larger particles dissolve more slowly than smaller particles, hence, the percentage dissolved during GI transit time increases as particle size decreases. Solubility of arsenic may be limited when insoluble matrix minerals (e.g., quartz) encase arsenic compounds. Similarly, formation of iron-arsenic oxides and phosphates, and prevalence of authigenic carbonate and silicate complexes also limit the solubility of arsenic (Davis et al., 1992, 1996). The solubility in the GI tract is complex since the pH conditions change from low pH in the stomach to a much higher pH in the small intestine. Readily soluble arsenic compounds, such as arsenate and arsenite, are more bioavailable than poorly soluble arsenic compounds, such as arsenic trioxide (ATSDR, 2000).

Several animal studies have evaluated the bioavailability of soil-bound arsenic. Results from Freeman et al. (1993 and 1995) and Groen et al. (1994) indicated that soil-bound arsenic is not as bioavailable as arsenic in solution. The bioavailability of soil arsenic relative to aqueous arsenic administered by gavage was approximately 20 percent in monkeys and 48 percent in rabbits. The higher relative bioavailability in rabbits reflected the higher absolute bioavailability in this species. This was much lower than the 64 to 69 percent of arsenic recovered in urine after ingestion of dissolved arsenic by human volunteers (Johnson and Farmer, 1991). Casteel et al. (1997) conducted a multi-year investigation of bioavailability of metals in soil and mine wastes using young swine whose GI system is more similar to humans than other animals. The relative bioavailability of arsenic in soils at various mining and smelting sites ranged from 7 to 52%, which agreed with the results of previous studies by Freeman at al. and Groen et al. Rodriguez et al. (1999) performed a similar swine study that reported the range of 2.7 to 42.8% relative bioavailability of arsenic in soil. Based on Gradient's literature review, a relative bioavailability of 50% is the maximum value reported in any of the peer-reviewed, published arsenic bioavailability studies. This evaluation used a relative bioavailability of 80%, based on guidance from USEPA Region 10. The relative bioavailability of 80% is thus likely to overestimate arsenic risks.

5.5.2.4 Cancer Slope Factor (CSF) for Arsenic

Reports on arsenic toxicity in humans are largely based on exposure to arsenic compounds in media other than soil, for example, consumption of drinking water and inhalation in occupational settings. USEPA has derived toxicity factors, *i.e.*, reference dose (RfD) and cancer slope factor (CSF), for ingested arsenic based on data from a Taiwanese study evaluating the health effects associated with the consumption of water containing high concentrations of arsenic (Chen *et al.*, 1985; Tseng *et al.*,

1968). Although the application of the population data used to derive the RfD and CSF has been heavily debated (Carlson-Lynch *et al.*, 1994; Smith *et al.*, 1995; Beck *et al.*, 1995; Mushak and Crocetti, 1995, 1996; Slayton *et al.*, 1996), the values derived are generally believed to be conservative.

The CSF is based on skin cancer observed in a study of over 40,000 people in Taiwan who were exposed for a significant portion of their lifetime to elevated levels of arsenic in groundwater. Although the study clearly indicates an association between high levels of arsenic exposure and cancer, the study design limits its usefulness to derive precise dose-response relationships. The reasons are summarized below:

Exposure Assessment. There are considerable scientific concerns about the exposure estimates in the Taiwanese study (USEPA Region 6, 1998). Individual exposures were not characterized, and exposures were based on average arsenic concentrations of ground water in wells in each village. The amount of exposure was broadly classified into three groups (high, medium and low) and the original data were not available. The analytical method used to measure arsenic concentrations may not be accurate at low levels.

Human-to-Human Variation. In general, dose levels, genetic factors, dietary patterns, or other life style factors may alter arsenic metabolism and detoxification in different populations (USEPA Region 6, 1998). Taiwanese may be more susceptible than U.S. population, and therefore CSF based on Taiwanese population may overestimate cancer for U.S. population. The protein deficiencies in Taiwanese diets could affect their ability to methylate and therefore detoxify arsenic, leading to an increase in cancer risk. Consequently, extrapolation from one population to another becomes highly uncertain.

Other Sources of Exposure. When the U.S. EPA derived the CSF, they did not take into account other possible sources of arsenic in the Taiwanese diet (e.g., from rice and yams) and dietary uses of drinking water. Hence, the assumptions used by the U.S. EPA in deriving toxicity values for arsenic underestimate the total arsenic intake, and as a result, the CSF may overestimate cancer risks.

Non-Linear Dose-Response. A recent U.S. EPA panel concluded that the dose-response for arsenic appeared to be non-linear (USEPA, 1997b), and the U.S. EPA Region 6 concluded that the available data "support a plausible threshold" (USEPA Region 6, 1998). The possible sublinear or threshold dose-response relationship suggests that cancer risk at low doses of arsenic may be less than predicted based on a linear model.

Arsenic Differs in Water and Soil. Health effects associated with arsenic in water may not be relevant to assess the toxicity in soil (Valberg et al., 1997). Arsenic exists in different chemical forms in water and soil, which may lead to potential differences in systemic bioavailability and dose-to-target organ. The relative proportion of overall arsenic intake and the correlation with urinary-arsenic concentrations may also be different between arsenic in water and soil. The differences will ultimately impact the overall potential for adverse health effects.

Overall, these uncertainties limit precise quantification of the dose-response relationship, but suggest the current CSF may overestimate cancer risks for a U.S. population exposed to lower levels of arsenic. Two recently published articles provide evidence that the CSF overestimates the cancer risk for arsenic as applied to drinking water studies outside the U.S. (Guo and Valberg, 1997) and within the U.S. (Valberg *et al.*, 1998). These papers report a meta-analysis of epidemiological studies evaluating the skin cancer incidence of 29 populations in India, Japan, Mexico, Taiwan and the U.S. who were exposed to 1.17 to 270 µg/L arsenic in water. The authors evaluated the validity of U.S. EPA arsenic CSF model to predict the expected number of skin cancers by conducting a likelihood ratio analysis. This analysis showed that a null hypothesis of no additional skin cancer risk from arsenic was approximately two times more likely than the hypothesis of the predicted rate of skin cancer from arsenic. This analysis indicated that the CSF derived from arsenic exposure in the Taiwanese populations is likely to be an overestimate when applied to the U.S. populations.

Additionally, in the epidemiological studies of a U.S. population that has been exposed to arsenic in drinking water, no increased cancer rate has been observed (USEPA Region 6, 1998). This is further supported by studies of individuals exposed to arsenic in soil who thus far have not indicated any toxicity (Binder *et al.*, 1987; Wong *et al.*, 1992).

5.5.2.5 Summary of Arsenic Risks and Uncertainty

Any effect of arsenic in soil on total arsenic body burden is difficult to observe as a result of the commonly reduced bioavailability of arsenic in soil, and the extent to which soil's contribution to body burden is overwhelmed by background levels of arsenic in food and water. Coupling these considerations with the uncertainty in the derivation of the arsenic cancer slope factor suggest that an acceptable risk level for soil arsenic may be close to 10^{-4} .

5.5.3 Uncertainties in Risk Characterization

Uncertainties associated with the first three steps of the risk assessment (data collection, exposure assessment, and toxicity assessment) are incorporated into the risk estimates in the risk characterization step. Although there are numerous uncertainties associated with this risk assessment, the incorporation of a large number of conservative assumptions has yielded risk estimates that are likely to overestimate actual site risks.

6 Soil Lead Cleanup Levels and Residual Risk

6.1 Soil Cleanup Levels

Lead risks are unacceptable for the construction worker in the main facility area, and the groundskeeper and the future site worker in the grassy area. Therefore, soil lead cleanup levels were calculated for these areas.

A preliminary remediation goal (PRG) is the average concentration in an exposure area that will result in an acceptable risk to a particular receptor. PRGs are risk-based target cleanup levels that must be met *on average* throughout the exposure area. It is acceptable to leave concentrations that exceed the cleanup level, so long as the post-remediation *average* concentration does not exceed the risk-based cleanup level.

The Remedial Action Level (RAL) is the concentration above which soil must be removed, so that the post-remediation average concentration meets the specified target cleanup level (USEPA, 2001b). The RAL is a remedial action goal (i.e., a remediation trigger concentration) that ensures the post-remediation average concentration at a site achieves the target cleanup level with a specified level of confidence.

PRGs for lead were calculated for subsurface soil (0-5 feet) in the main facility area and surface soil (0-6 inches) in the grassy area (Table 7). In the main facility area, the PRG for lead in subsurface soil is 4600 mg/kg for the construction worker. In the grassy area, the PRG for surface soil is 3195 mg/kg for the future site worker.

RALs were calculated for these two receptors, assuming that excavated soil would be replaced with clean backfill containing lead at 50 mg/kg. The RAL for the main facility area is 78,900 mg/kg for subsurface soil. The RAL for surface soil in the grassy area is 16,700 mg/kg.

6.2 Post-Remediation Residual Risk

The residual risk from arsenic was calculated assuming that soil was remediated to the lead RAL in the main facility area and the grassy area. The post-remediation arsenic EPCs for these two exposure areas were calculated (using ProUCL) assuming that excavated soil was replaced with clean backfill

containing arsenic at 5 mg/kg. The post-remediation arsenic EPCs are 41.2 mg/kg in the main facility area, and 40.7 mg/kg in the grassy area (Table 8). Both of these EPCs were the nonparametric UCL calculated with the "bootstrap-t" method. Residual cancer risks range from 3×10^{-7} to 8×10^{-6} (Table 8). Residual noncancer risks range from 0.01 to 0.1 (Table 8).

Table 8
Summary of Post-Remediation Risks for Arsenic

| | | | Baseline | Post Remediation | Post Remediation | Post Remediation |
|----------------------------------|-----------------|-----------------------|---------------------------|---------------------------|---|-----------------------|
| Exposure Area | Medium | Receptor | Arsenic EPC (mg/kg) | Arsenic EPC (mg/kg) | Total Excess Lifetime Cancer Risk | Total Hazard Index |
| Main Plant Area | Subsurface soil | Construction Worker | 123 | 41.2 | 2E-06 | 0.1 |
| William Facu | 5403411400 3011 | Utility Worker | 123 | 41.2 | 1E-06 | 0.02 |
| | | Future Site Worker | 312 | 40.7 | 6E-06 | 0.04 |
| Grassy Areas | Surface soil | Groundskeeper | 312 | 40.7 | 4E-06 | 0.03 |
| | | Adolescent Trespasser | 312 | 40.7 | 3E-07 | 0.01 |
| Off Site Natural Gas Facility | Surface soil | Adult Worker | 28.5 | 28.5 | 8E-06 | 0.05 |

7 Conclusions

Cancer risks attributable to arsenic were calculated for receptors in three exposure areas. All of the calculated cancer risks fall within USEPA's target risk range of 1×10^{-6} to 1×10^{-4} . The exposure scenario with the highest excess lifetime cancer risk is the future site worker in the grassy area (4×10^{-5}) . The exposure pathway with the greatest contribution to cancer risk is soil ingestion.

Noncancer risks attributable to arsenic were calculated for receptors in three exposure areas. All of the calculated noncancer risks are below USEPA's target hazard index of 1.0. The exposure scenario with the highest noncancer risk is the onsite construction worker (HI of 0.4). The exposure pathway with the greatest contribution to noncancer risk for the resident is soil ingestion.

Lead risks were evaluated for adult and/or adolescent receptors in three exposure areas. Lead risks were evaluated by comparing the predicted fetal BLL for each receptor to USEPA's BLL goal of 10 µg/dL. Predicted 95th percentile fetal BLLs exceeded USEPA goals for the construction worker exposed to subsurface soil in the main facility area, and the groundskeeper and future site worker exposed to surface soil in the grassy area. The predicted 95th percentile fetal BLL did not exceed the USEPA goal for the offsite gas facility worker.

The residual risk from arsenic was calculated assuming that soil was remediated to the lead RAL in the main facility area and the grassy area. Residual cancer risks range from 3×10^{-7} to 8×10^{-6} , and residual noncancer risks range from 0.01 to 0.1.

- 2

1.0 INTRODUCTION

Presented herein, is the Phase I Corrective Measures Study (CMS) Report for the Refined Metals Corporation (RMC) facility in Beech Grove Indiana. Pursuant to the CMS Work Plan, approved by USEPA in a letter dated November 5, 2003, this report has been prepared to present the results of the additional sampling activities and the preliminary risk assessment results. A description of the activities is provided in the following sections. Copies of the completed documents are provided as attachments.

2.0 FIELD ACTIVITIES

Based on an evaluation of previous investigation results following the Phase II RCRA Facility Investigation (RFI), a determination was made that additional characterization sampling was required for sediment and groundwater at the RMC Site. The sediment sampling consisted of collecting additional samples from the drainage ditch along the CSX Transportation railroad right-of-way north of the facility and from the grass lined drainage ditch along the west side of Arlington Avenue. Sediment samples were collected from 6 locations along the railroad drainage ditch and 4 locations in the Arlington Avenue drainage ditch. Two samples were collected at each location. Along Arlington Avenue, one sample was collected from the 0 to 6inch depth and the second from the 6 to 12-inch depth. Along the railroad right-of-way, they were collected from 0 to 3 inches and 3 to 10 inches.

Groundwater sampling included the installation of three piezometers in the area north and east of the former manufacturing area. The piezometers were installed with the intent of further refining groundwater flow direction prior to selection of locations for the new monitoring wells. The piezometers were allowed to set for 24 hours before groundwater level measurements were taken from the existing shallow monitoring wells at the north end of the former manufacturing area and the piezometers. Groundwater flow direction was re-assessed based on the measurements and the locations for two new groundwater-monitoring wells were selected. The new groundwater monitoring wells were installed using hollow stem auger (HSA) drilling techniques. piezometers were abandoned after groundwater level measurements were taken. Groundwater samples were collected from all the Site groundwater monitoring wells between October 26 and 28, 2004 using low flow sample collection techniques.

A complete description of the sediment and groundwater sampling activities is provided in the Phase I CMS Activities Summary Report which is provided as Attachment 1 to this report.

3.0 ANALYTICAL RESULTS

3.1 GROUNDWATER

Shallow groundwater at the Site is perched and discontinuous and is not used for any purpose. Groundwater samples collected from the shallow groundwater monitoring wells in the north end of the former manufacturing area (MW-2, 7 and 8) gave unfiltered results for total lead in excess of the Indiana Department of Environmental Management (IDEM) Residential Default RISC Criteria (15 ug/L). Analysis of filtered groundwater samples from those wells for lead from the same sampling event were at or below the IDEM Residential Default RISC Criteria. Filtered and unfiltered results for arsenic in MW-1, MW-2, MW-7 and MW-8, and unfiltered results only for MW-3, MW-5 and MW-10 were above the background concentration for arsenic (8.5 µg/l) calculated in the Phase II RFI. No other parameters for MW-2, MW-7 and MW-8 or any of the parameters analyzed for any other well on-site exceeded the IDEM Residential Default RISC Criteria.

3.2 SEDIMENT

Concentrations of lead in the shallow surface sediment samples collected at the depth of 0-3 inches ranged from 617 mg/kg to 14,800 mg/kg and concentrations or arsenic ranged from 12 mg/kg to 169 mg/kg at this depth. Concentrations of lead in the shallow surface sediment samples collected at the depth of 0-6 inches ranged from 411 mg/kg to 874 mg/kg and concentrations of arsenic ranged from 11 mg/kg to 12 mg/kg at this depth. The calculated background for arsenic in shallow surface soil (10.5 mg/kg) was exceeded in all samples. The cleanup level for lead calculated in the Human Health Risk Assessment (Attachment 2)(15,916 m/kg) was not exceeded in these samples.

Concentrations of lead in the subsurface sediment samples collected at the depth of 3-10 inches ranged from 403 mg/kg to 15,700 mg/kg and concentrations of arsenic ranged from 9 mg/kg to 216 mg/kg at this depth. Concentrations of lead in the samples collected at the depth of 6-12 inches ranged from 24 mg/kg to 1,470 mg/kg and concentrations of arsenic ranged from 8.3 F:\OFICEAGC\PROJECTS\Files\2003-1046\Reports\Corrective Measures\Phase I text.doc 3-1

mg/kg to 15 mg/kg at this depth. The calculated background concentrations for arsenic in subsurface soil (7.9 mg/kg) was exceeded in all samples. The calculated cleanup level for lead (15,916 mg/kg) was not exceeded in these samples.

4.0 PRELIMINARY RESULTS OF RISK ASSESSMENT

Gradient Corporation (Cambridge, MA) conducted the Baseline Human Health Risk Assessment (Risk Assessment) for RMC. Pursuant to the CMS Work Plan, the Risk Assessment evaluated a variety of exposure scenarios for lead and arsenic for workers at the facility and on the adjacent Citizens Gas property. The evaluation determined that existing arsenic levels at the Site do not present an unacceptable risk for the exposure scenarios evaluated. The lead risk evaluation determined that soil lead concentrations in some areas of the Site create a predicted (95% UCL) blood lead >10ug/dl for the construction worker in the "on-site" area, and for the groundskeeper and plant worker in the "grassy area".

Results of the risk assessment include a Preliminary Remediation Goal (PRG) for each of the exposure scenarios which predict a 95% UCL blood lead >10 ug/dl. The model also provides a Remedial Action Level (RAL), which represents the soil cleanup concentration that will result in remaining soil having an average soil lead concentration less than the PRG. The concept of a RAL is consistent with the adult lead model, which recognizes that the model evaluates exposure on an area wide basis. This means that soils with concentrations exceeding 78,900 mg/kg must be remediated in the "on-site" area to result in an average lead concentration less than 4,601 mg/kg. For the grassy site area (which also includes the wooded areas), the PRG and RAL are 3,195 and 16,700 mg/kg, respectively. The PRG for the Citizens Gas property is 1,840 mg/kg, which is higher than the average soil lead concentration; therefore, no remediation is necessary on the Citizens Gas property.

The complete Baseline Human Health Risk Assessment report is provided as Attachment 2.

5.0 CONCLUSION

Based on the results of the Risk Assessment, arsenic does not pose an unacceptable risk in surface or subsurface soils at the Site. Therefore, no soil remediation is necessary for arsenic.

A conclusion of the Baseline human Health Risk Assessment is that soil remediation is necessary in the "on-site" plant area to remove subsurface soil with total lead concentrations that exceed the calculated RAL of 78,900 mg/kg. Because the exposure scenario assumes a worker who is performing intrusive activities, this standard is being applied to areas with and without pavement.

For the "grass areas", which includes all areas of the site excluding the "on-site" area, the RAL is 16,700 mg/kg for surface soils and no remediation is required for subsurface soils (i.e., soils deeper than 6 inches). Additionally, because the exposure scenario anticipates a non-intrusive use, no removal will be proposed beneath areas of existing pavement. The drainage ditches are considered to be part of the "grass areas" and will therefore be remediated to the 16,700 mg/kg RAL.

1.0 INTRODUCTION

1.1 GENERAL

This Corrective Measures Study Activities Summary Report has been submitted by Advanced GeoServices Corp. (AGC) on behalf of Refined Metals Corporation (RMC). This report presents and discusses the methods and procedures used to implement the scope of work as proposed in the Phase II RCRA Facility Investigation (RFI) Report. Groundwater monitoring well installation and sampling activities were conducted by AGC. These activities consisted of installing three piezometers and two groundwater monitoring wells, groundwater sampling and sediment sampling at on-site and off-site locations. Laboratory sample analysis was performed by TriMatrix Laboratories Inc. (TriMatrix) of Grand Rapids, Michigan.

The RMC facility was the location of secondary lead smelting operations from 1968 through 1995. RMC was involved in the reclamation of lead from used automotive and industrial batteries and other lead bearing materials. The Site ceased smelting operations on December 31, 1995. Additional background and facility operation can be found in the Phase II RCRA Facility Investigation Report, dated November 18, 2002.

During its operational life, the facility handled materials that were classified as hazardous materials or hazardous wastes under the Resource Conservation and Recovery Act (RCRA). At this time, the Site is idle except for the wastewater treatment system which remains in operation. The wastewater treatment system remains in place to collect and treat stormwater runoff from the lined lagoon and other Site areas.

2.0 WELL INSTALLATION ACTIVITIES

2.1 INTRODUCTION

Background and facility operation information can be found in the Phase II RCRA Facility Investigation Report, dated November 18, 2002. During the Corrective Measures Study (CMS) three temporary piezometers and two groundwater monitoring wells were installed by Boart Longyear, Environmental Division, from Greensberg, Indiana. The three piezometers were installed using a truck mounted Geoprobe in the area north and east of the former manufacturing area. The piezometers were installed for the purpose of refining groundwater flow prior to selection of locations to install two new wells. Geoprobe borings were advanced into the shallow perched groundwater and the piezometer was constructed using a one (1) inch diameter PVC 0.010 screen. The piezometers were constructed on September 4, 2003 as follows:

| | Depth of Boring | Depth of Piezometer | Screen Length | GW Elevation 9/05/2003 |
|------|--------------------|------------------------|------------------|---------------------------|
| GP-1 | 20' | 18.0' | 15' | 837.63 |
| GP-2 | 15' | 14.8' | 10' | 839.30 |
| GP-3 | 25' | 23.5' | 15' | 877.89 |

Groundwater level measurements were taken from the existing monitoring wells north of the former manufacturing area and piezometers on September 5, 2003 and the locations for two new groundwater-monitoring wells were selected.

The two groundwater monitoring wells were installed between September 8-10, 2003 and designated as MW-10 and MW-11. Groundwater monitoring well MW-10 is located east of MW-2 within the wooded area as shown on Figure 2-1. The depth of the boring for MW-10 was recorded to be 36 feet below ground surface (bgs). Groundwater monitoring well MW-11 is located approximately 156 feet east of MW-8 along the fence line of Arlington Avenue. The

depth of the boring for MW-11 was measured at 30 feet bgs. The locations of both wells installed are shown on Figure 2-1.

2.1.1 <u>Drilling Methods</u>

The soil borings were advanced using hollow stem auger (HSA) techniques and continuous split spoon samples were collected in accordance with ASTM D 1586. The logs for the borings and well construction completed as part of this investigation are included in Appendix A. The samples recovered from the advancement of the deep borings were logged and described using USCS soil classification.

2.1.2 Groundwater Monitoring Well Construction

The monitoring wells were constructed using a 4-inch ID, flush-threaded, Schedule 40 PVC riser with a 10-foot length of factory-slotted 0.010-inch PVC well screen. A sand pack was placed to 2 feet above the top of the monitoring well screen with No. 5 sand. A minimum 2-foot thick bentonite seal was placed on top of the sand pack.

All monitoring wells were completed with a steel protective casing with a locking cap. The protective casing extends from an approximate depth of 3 feet bgs to approximately 2 feet above ground. A neat cement seal was placed around the protective casing to a depth of 2.5 to 3 feet bgs. A 2-foot square well pad was installed so that the surface slopes away from the well.

2.1.3 Groundwater Monitoring Well Development Method

Each groundwater monitoring well installed as part of this Corrective Measures Study field activities were developed using the surge-block and pump method. Groundwater monitoring wells were first surged using a plunger-type surge block assembly. This provides the necessary turbulence in and immediately surrounding the well screen to remove fine-grained material. The wells were then purged and developed by continuous pumping using a electric submersible

pump. Well development ceased when the development water in each well was relatively sediment free, exhibited a satisfactory visual clarity and yield.

2.2 GROUNDWATER SAMPLING

2.2.1 Groundwater Well Evacuation

Following the installation of the two additional groundwater monitoring wells, groundwater samples were collected. The sampling event took place on October 26-29, 2003. Groundwater samples were obtained from groundwater monitoring wells MW-1, MW-2, MW-3, MW-4, MW-5, MW-6SR, MW-7, MW-8, MW-9, MW-10 and MW-11. A total of 11 groundwater samples were collected at the Site (excluding QA/QC samples). A low-flow sampling technique was employed to more accurately determine the potential for site-related constituents which may have entered the groundwater.

Each groundwater monitoring well was purged using a stainless steel low-flow bladder pump placed at the midpoint of the screen in each well. The wells were purged at a flow rate ranging from 100 to 300 milliliters per minute mls/min, depending on the yield of the well. A flow-through cell was used to measure the following field parameters: pH, temperature, conductivity, redox potential, and dissolved oxygen prior to contact with oxygen. These parameters were collected at 3 to 5 minute intervals during purging event. Turbidity was also measured at the same time interval. The wells were purged until the field parameters stabilize to within 10% over three readings and pH readings differ by less than 0.1 unit.

2.2.2 Groundwater Sample Collection

Once the field parameters had stabilized, samples were collected directly from the pump discharge line into laboratory-supplied bottles containing the necessary preservatives at a sampling flow rate of 100 to 300 mls/min.

Sample containers were labeled with a unique identifying number, time and date of sample collection, requested analysis, preservative, and the initials of the sample collector. Samples were packed on ice and shipped to TriMatrix Laboratories Inc. for analysis of eight RCRA metals and antimony (SW-846 6010). Samples for dissolved metals analyses were field filtered through a dedicated disposable Nalgene 0.45 µm membrane filter immediately after collection and prior to preservation. The sample was decanted into the dedicated, Nalgene disposable filtration unit and filtered under vacuum pressure created by a hand-held pump. The sample was then immediately transferred to a laboratory supplied bottleware.

3.0 SEDIMENT SAMPLING

Sediment samples were collected from four locations along the drainage ditch running parallel to Arlington Avenue and from six locations along the CSX rail line drainage ditch. The samples collected along the Arlington Avenue drainage ditch were designated R2SED-11 through R2SED-14. The samples collected along the CSX line were designated R2SB25 through R2SB-30. The location of the sediment samples are presented on Figure 3-1. Sediment was collected at depth intervals of 0-6 inches and 6-12 inches bgs at each of the R2SED locations. Sediment was collected at depth intervals of 0-3 inches and 3-10 inches bgs at each of the R2SB locations. The depth of collection was placed as a suffix to each sample location to delineate in which depth the result is correlated. All sediment samples were collected using decontaminated hand augers. The sediment from each interval was thoroughly homogenized in an aluminum mixing pan and was placed directly into a laboratory supplied jar. Each sediment sample was then placed on ice for shipment and was submitted to TriMatrix to be analyzed for arsenic and lead (EPA Method SW-846 6010B).

4.0 RESULTS

4.1 GROUNDWATER

4.1.1 Groundwater Screening

Arsenic and lead are the two site constituents of concern (COCs) that were detected at levels above the concentrations used for initial groundwater screening purposes. A background concentration was calculated for initial screening of arsenic in groundwater. The background concentrations for arsenic in groundwater has been calculated to be $8.5~\mu g/l$, which is the mean concentration taken from MW-9 plus one standard deviation. The current EPA Region 9 Preliminary Remediation Goals for Tap Water do not provide a standard for lead in groundwater; therefore, we are utilizing the Indiana Department of Environmental Management (IDEM) Residential Default RISC criteria of 15 $\mu g/l$. The IDEM Residential Default RISC criteria for arsenic is 50 $\mu g/l$.

4.1.2 Groundwater Sampling Results

The analytical results for samples collected from the on-site wells for the groundwater sampling event are presented in Table 4-1. A groundwater surface map is shown as Figure 4-1. October 2003 sample results are provided in Figure 4-2.

Total arsenic was found in groundwater samples at concentrations ranging from 1.3 μ g/l in MW-4 to 290 μ g/l in MW-7. Arsenic concentrations were detected above the background concentration in MW-1 (24 μ g/l), MW-2 (15 μ g/l), MW-3 (28 μ g/l), MW-5 (8.8 μ g/l), MW-7 (290 μ g/l), MW-8 (19 μ g/l) and MW-10 (24 μ g/l). Only MW-7 exceeded the IDEM Residential Default RISC Criteria for arsenic in groundwater.

Total lead was found in groundwater samples at concentrations ranging from below laboratory detection level in MW-1, MW-3, MW-4, MW-10, and MW-11 to 217 μ g/l in MW-7. Lead concentrations were detected above the IDEM Residential Default Risk Criteria concentration in MW-2 (44 μ g/l), MW-7 (217 μ g/l) and MW-8 (55 μ g/l). The only filtered sample at or above 15 μ gl was MW-8 at a concentration of 15 μ gl.

4.2 <u>SEDIMENT</u>

4.2.1 Sediment Screening

Arsenic and lead are the two site constituents of concern (COCs) that were detected at levels above their initial screening levels for soil and sediment. Samples collected from the drainage ditches are referred to as sediment in this report; however, because of the physical character of the material sampled and geomorphic setting, they are compared to the soil standards. The calculated background arsenic in soil concentrations are 10.53 mg/kg for surface soil (0-3 inch) and 7.91 mg/kg (>3 inches) for subsurface soils. Based on the Baseline Human Health Risk Assessment (Attachment 2), the target cleanup level for lead in soil at the Site is 15,916 mg/kg for surface (0-6 inches) soil.

4.2.2 <u>Sediment Sampling Results</u>

The validated analytical results for the sediment samples collected within the drainage ditch along Arlington Avenue and the drainage ditch along the CSX rail line are provided in Table 4-2. The depth of collection was placed as a suffix to each sample location to delineate to show to which depth the result is correlated.

Concentrations of lead in the samples collected at the depth of 0-3 inches ranged from 617 mg/kg at R2SB25 to 14,800 mg/kg at R2SB29, and concentrations of arsenic ranged from 12 mg/kg at R2SB30 to 169 mg/kg at R2SB26 at this depth. The calculated background concentration for

arsenic was exceeded in all samples. The Baseline Human Health Risk Assessment (HHRA) cleanup level for lead was not exceeded in these samples.

Concentrations of lead in the samples collected at the depth of 0-6 inches ranged from 411 mg/kg at R2SED-12 to 874 mg/kg at R2SED-11, and concentrations of arsenic ranged from 11 mg/kg at R2SED-14 and R2SED-12 to 12 mg/kg at R2SED-11 and R2SED-13 at this depth. Table 4-2 presents lead and arsenic results within this depth interval. The calculated background concentration for arsenic was exceeded in all samples. The HHRA cleanup level for lead was not exceeded in these samples.

Concentrations of lead in the samples collected at the depth of 3-10 inches ranged from 403 mg/kg at R2SB28 to 15,700 mg/kg at R2SB29, and concentrations of arsenic ranged from 9 mg/kg at R2SB30 to 216 mg/kg at R2SB29 at this depth. Table 4-2 presents lead and arsenic results within this depth interval. The calculated background concentration for arsenic was exceeded in all samples. The HHRA cleanup level for lead was not exceeded in these samples.

Concentrations of lead in the samples collected at the depth of 6-12 inches ranged from 24 mg/kg at R2SED-14 to 1,470 mg/kg at R2SED-11, and concentrations of arsenic ranged from 8.3 mg/kg at R2SED-13 to 15 mg/kg at R2SED-11 at this depth. The calculated background concentration for arsenic was exceeded in all samples. The HHRA cleanup level for lead was not exceeded in these samples.

5.0 **SUMMARY**

The following are drawn from the findings of the Corrective Measures Study activities:

Groundwater

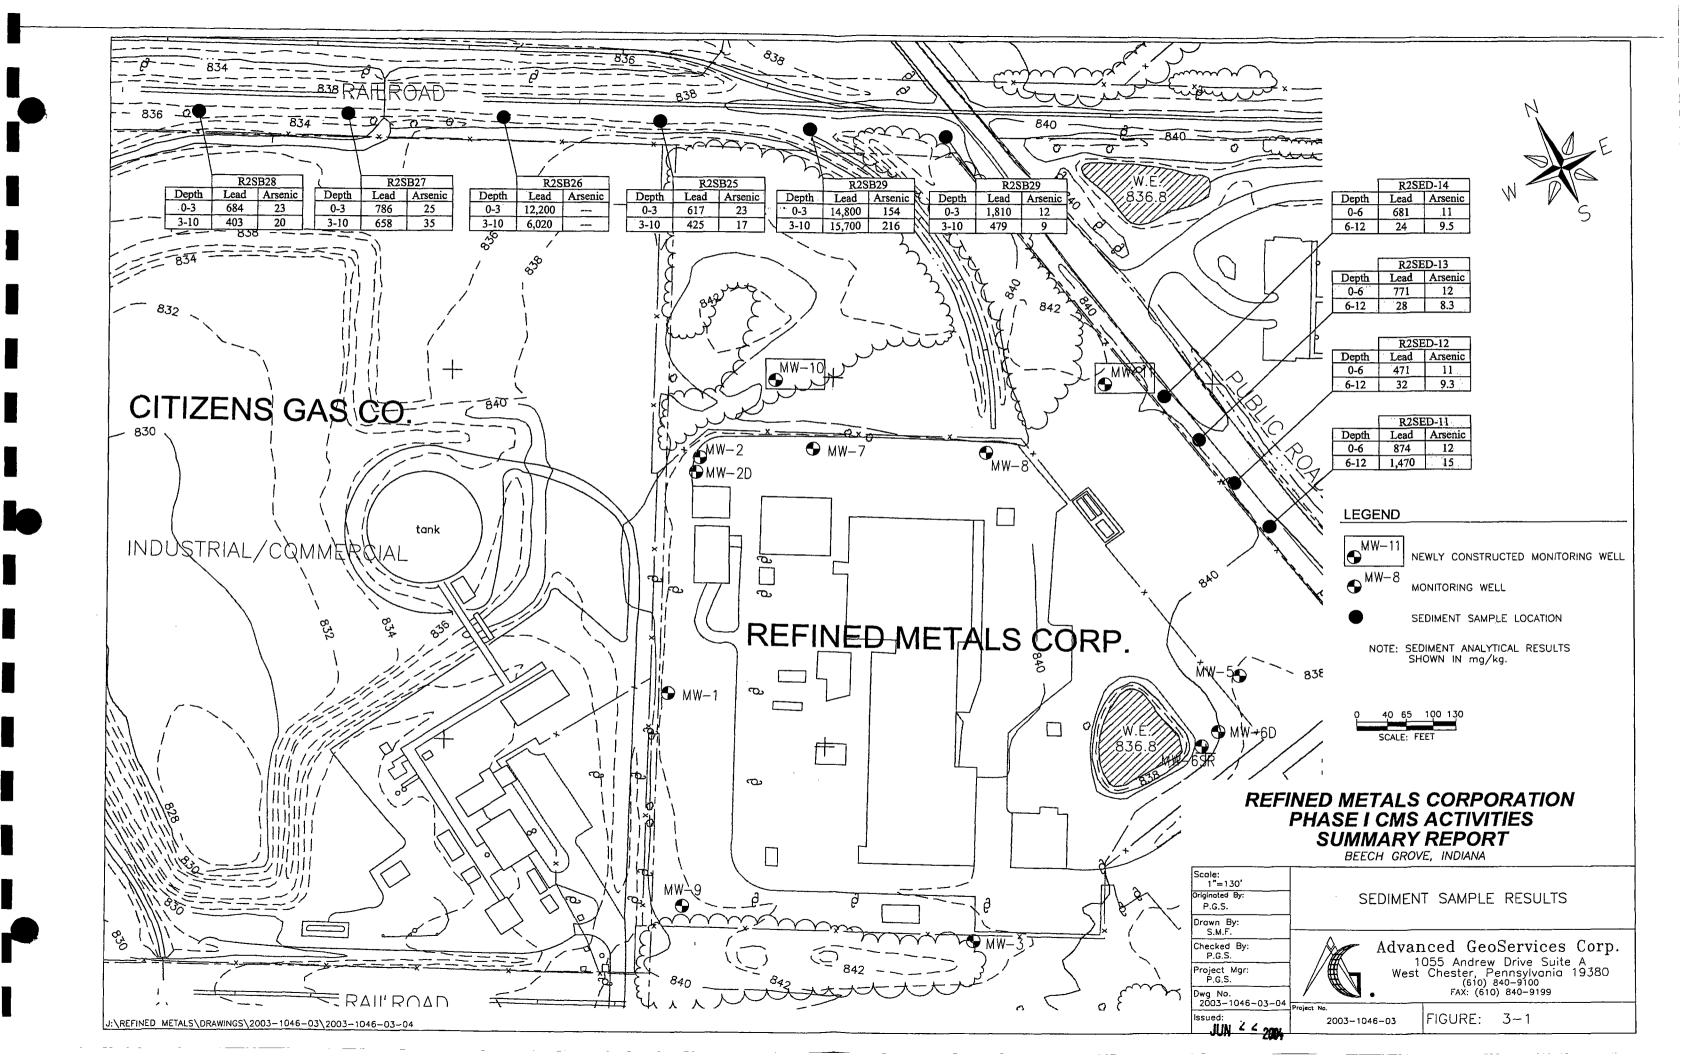

- Groundwater flow in the shallow zone of saturation on-site appears to be to the south-southeast.
- Arsenic concentrations exceeded the calculated background concentration in all but four of the samples tested.
- Lead detected above the IDEM Residential Default RISC Criteria is limited to MW-2S (18 μg/l), MW-7S (217 μg/l) and MW-8S (28 μg/l) immediately north of the manufacturing area where elevated soil lead concentrations exist.

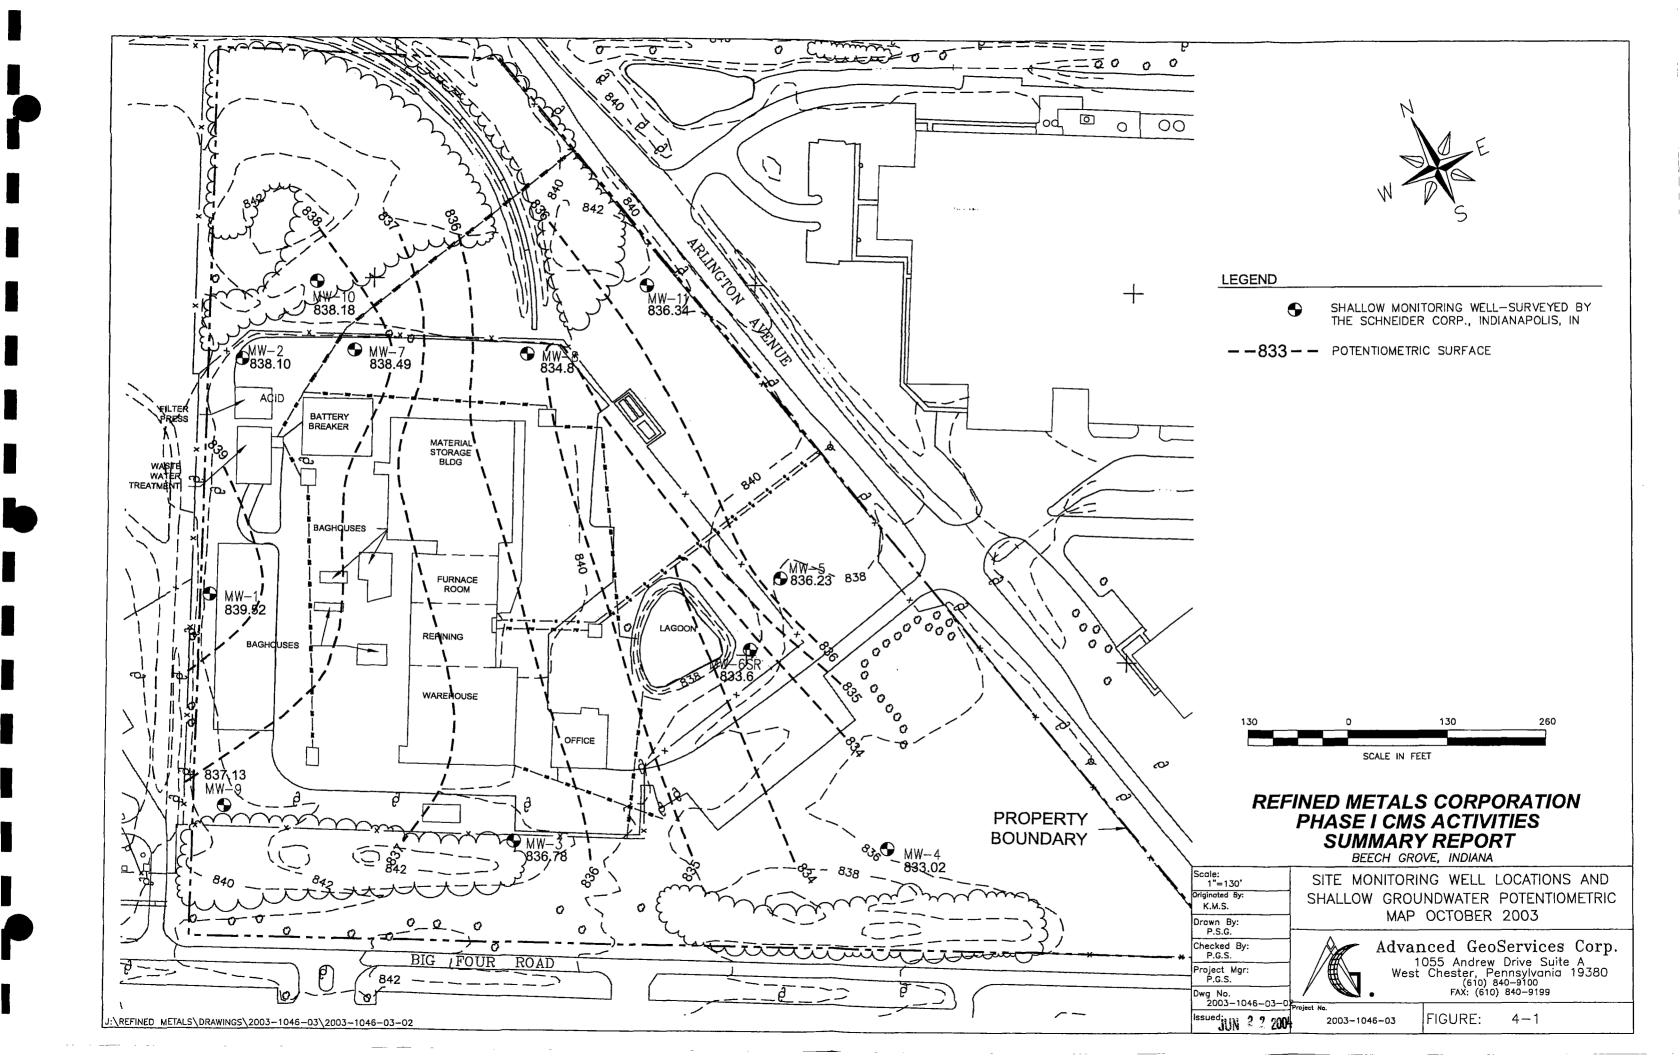

Sediment

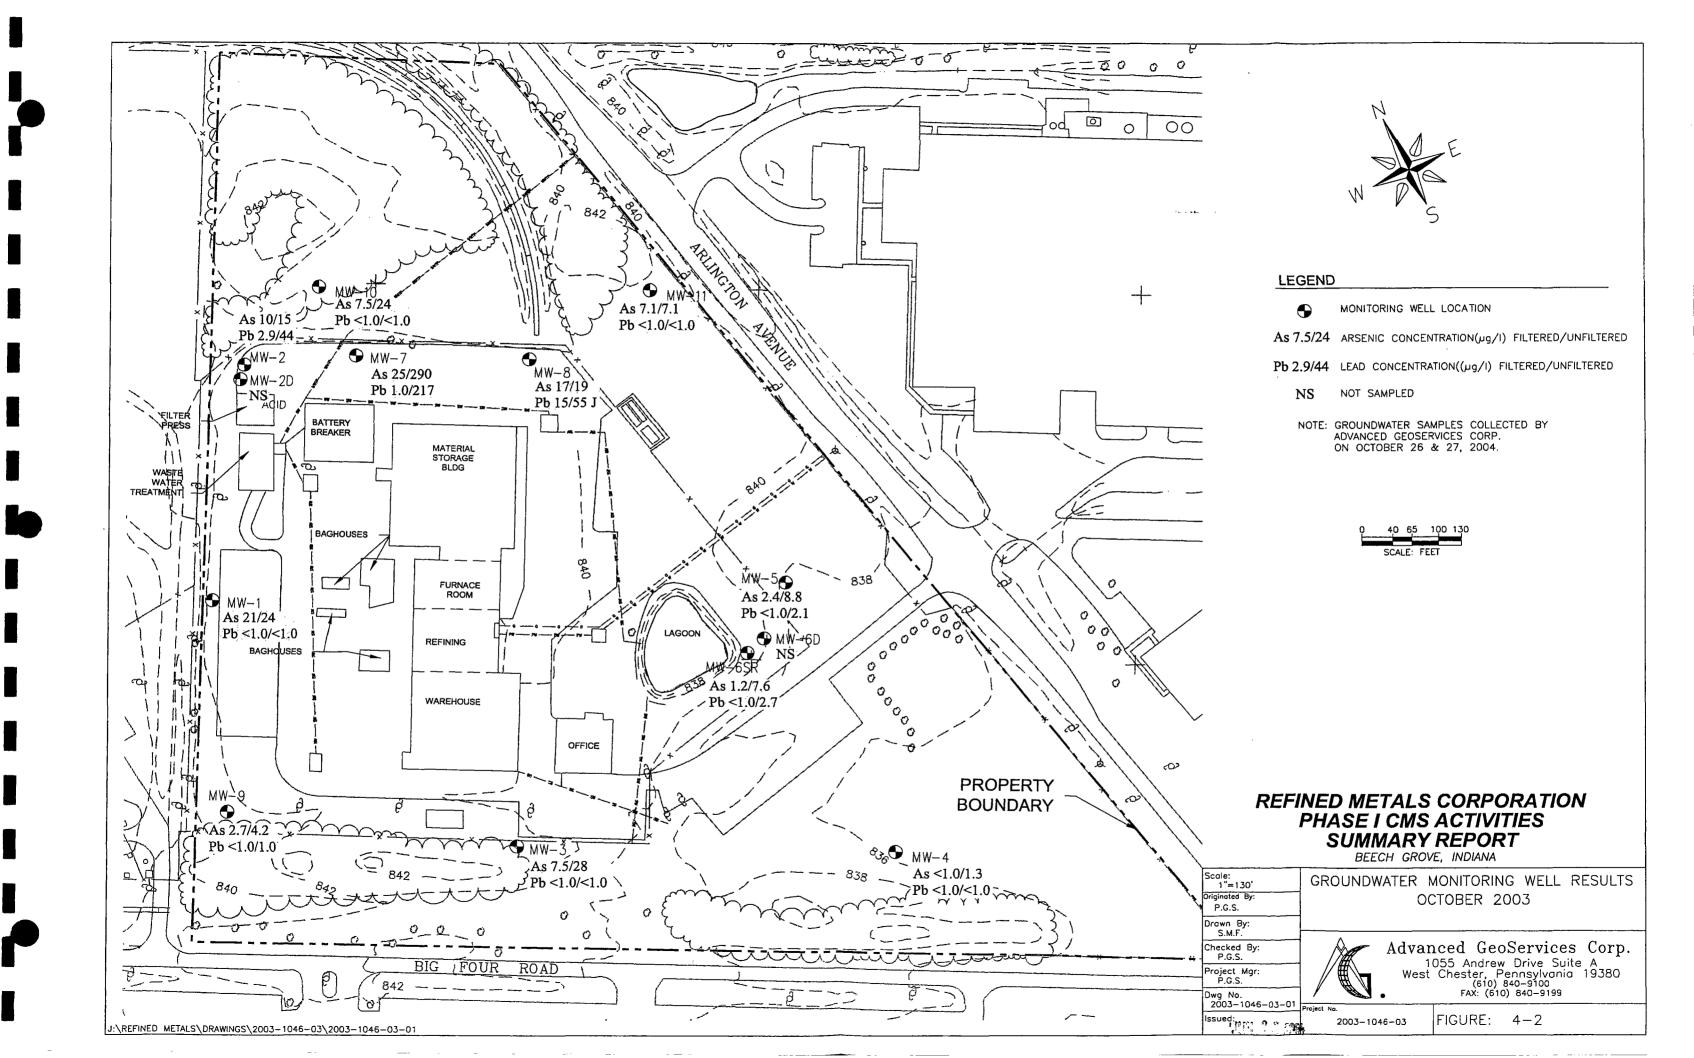

- Elevated arsenic in sediment in the drainage ditch along Arlington Avenue and along the CSX line northeast of the Site indicate that off-site transport of sediment may have occurred.
- All sediment sample results for lead are shown to be below the RAL calculated in the Baseline Human Health Risk Assessment.

1 Introduction

1.1 Site Description and History

The Refined Metals Corporation (RMC) facility is located at 3700 South Arlington Avenue in Beech Grove, Indiana. Secondary lead smelting and refining operations were conducted at this site from 1968 to the end of 1995.

The site occupies approximately 24 acres, of which approximately 10 acres represented the active manufacturing area (including paved areas and buildings). The remaining 14 acres includes grassed and wooded site areas. The site is bordered by Arlington Avenue to the east, a natural gas facility (Citizen's Gas) to the west, a railroad to the north, and Big Four Road to the south (Figure 1). The site is relatively flat with less than 10 feet of total relief. Natural site drainage is toward the north and east. The former manufacturing area is almost completely paved, and is characterized by nearly 80,000 square feet of structures consisting of the battery breaker, a wastewater treatment plant, material storage areas, a blast furnace, a dust furnace, a metals refining area, warehouse and offices.

The RMC facility was divided into two exposure areas for the purpose of this evaluation: the fenced facility area consisting of the plant buildings and surrounding paved areas; and the grassy areas to the north, east, and south of the paved facility area. The Citizen's Gas property to the west was evaluated as a separate exposure area.

1.2 Previous Investigations

On July 14, 1998, RMC entered into a Consent Decree with the United States Environmental Protection Agency (USEPA) and the Indiana Department of Environmental Management (IDEM). Under this Consent Decree, a RCRA Facility Investigation (RFI) was performed to evaluate and determine the nature and extent of releases and to collect information necessary to support human health and ecological risk assessments so that a Corrective Measures Study may be implemented. Pursuant to Section VI, Paragraph 42 of the Consent Decree (Compliance Requirements for Corrective Action), Advanced GeoServices Corp. (AGC) performed the RFI in accordance with an approved RFI work plan on behalf of RMC. The preparation and implementation of the RFI work plans were enacted in accordance with Exhibit B of the Consent Decree and the EPA's RCRA Facility Investigation Guidance Document (EPA 530/SW-89-031). The RFI was conducted in multiple phases. The results from the initial phase of sampling were presented in the Phase I RFI Report dated August 31, 2000. Based on the results of the Phase I RFI a Phase II RFI Work Plan was submitted to the EPA on December 20, 2000. In response to comments on the Phase II RFI Work Plan issued by the EPA on April 3, 2001, revisions to the Phase II RFI Work Plan were submitted to the EPA on June 27, 2001. The EPA approved the Phase II RFI Work Plan on July 13, 2001, the results of which were contained in the Phase II RFI Report dated November 18, 2002. Additional site sampling was conducted during a closure investigation to address three former RCRA-regulated solid waste managements units (SWMUs). The results of the SWMU closure investigation were presented by AGC in the Closure Investigation Report dated June 1, 2001.

1.3 Report Objectives and Organization

This report presents the results of the baseline human health risk assessment (HHRA) that was conducted to evaluate potential human health risks in each exposure area. The purpose of this evaluation 203030

is to determine whether these areas pose any significant health risks or if they require remediation to reduce risk to acceptable levels.

The remainder of this report is organized in the following sections. Section 2 discusses the data used in the risk assessment, and the constituents of potential concern. Section 3 discusses the potential receptors, exposure media, and exposure pathways for each exposure area. Section 4 presents the toxicity assessment. Section 5 presents the risk characterization. Section 6 presents soil lead cleanup levels. Section 7 presents the conclusions for all scenarios evaluated.

2 Constituents of Potential Concern

The results of the Phase I RFI indicated that lead and arsenic are the main contaminants of concern in soil, both onsite and offsite. Lead and arsenic were detected in soil samples from the site at concentrations above both residential and industrial risk-based concentrations (RBCs). The baseline risk assessment retained lead and arsenic as COPCs in soil.

3 Exposure Assessment

3.1 Potential Receptors and Exposure Pathways

The potential receptors, exposure media, exposure pathways, and exposure frequencies evaluated in each exposure area are presented in Table 1, and are discussed in more detail below.

Table 1
Receptors and Exposure Pathways

| Exposure Area | Media | Soil Depth | Exposure Pathways | Receptors | Exposure Frequency (days/year) | Exposure Duration (years) |
|-------------------------------------|-----------------|---------------|---------------------------------|--------------------------|--------------------------------------|---------------------------------|
| Plant Area | Subsurface soil | 0-5 ft | Ingestion, Dermal Contact | Construction Worker | 50 | 5 |
| Plant Area | Subsurface soil | 0-5 ft | Ingestion, Dermal Contact | Utility Worker | 10 | 10 |
| North, | | | Ingestion, | Groundskeeper | 50 | 25 |
| South, and East Grassy | Surface soil | 0-6" | Dermal Contact | Adolescent Trespasser | 25 | 5 |
| Areas | | | Contact | Future Site Worker | 144 | 25 |
| Off Site Natural Gas Facility | Surface soil | 0-6" | Ingestion, Dermal Contact | Adult Worker (30 yr) | 225 | 25 |

3.1.1 Facility Area

The plant buildings and surrounding paved areas occupy approximately the central third of the RMC property. The site is largely paved – the only exposed surface soil is limited to a strip along the western fence line. In this exposure area, we evaluated a utility worker and a construction worker who could be exposed to subsurface soil. Both the utility and construction worker are assumed to be exposed to subsurface soil at depths from 0 to 5 feet, *via* incidental ingestion and dermal contact. The utility worker is assumed to have an exposure frequency of 10 days/year and an exposure duration of 10 years. The construction worker is assumed to have an exposure frequency of 50 days/year for 5 years.

3.1.2 Grassy Areas North, South, and East of Main Facility

The grassy and wooded areas located north, south, and east of the main facility encompass approximately the northern and southern thirds of the RMC property (Figure 1). The receptors evaluated in both of these areas include an adolescent trespasser and an adult groundskeeper under current use, and a future site worker. These receptors are assumed to be exposed to surface soil *via* incidental ingestion and dermal contact. The adolescent trespasser (age 13-18 years) is assumed to have an exposure frequency of 25 days/year and an exposure duration of 5 years. The groundskeeper is assumed to have an

exposure frequency of 50 days/year and an exposure duration of 25 years. A future site worker is assumed to spend most of his time in the plant and surrounding paved areas. However, he may have occasion to visit the grassy/wooded areas for a walk or to eat lunch at a picnic table. The future site worker is assumed to have an exposure frequency in these areas of 4 days/week for 36 weeks/year or 144 days/year, and an exposure duration of 25 years.

3.1.3 Offsite Natural Gas Facility

At the offsite natural gas facility, an adult commercial worker was evaluated. The worker is assumed to be exposed to surface soil *via* incidental ingestion and dermal contact. The worker is assumed to have an exposure frequency in these areas of 5 days/week for 45 weeks/year, or 225 days/year, and an exposure duration of 25 years.

3.2 Exposure Point Concentrations

In a risk assessment, an Exposure Point Concentration (EPC) represents the concentration of a chemical in an environmental medium to which an individual is exposed. The calculation of EPCs is described below. The EPCs used in this risk evaluation are presented in Table 2.

Table 2
Exposure Point Concentrations

| Exposure Area | Medium | Depth | Arsenic | | Lead | |
|---------------------------------|--------------------|--------|--------------|-----------------|--------------|-----------------|
| | | | EPC mg/kg | Basis 95%UCL | EPC mg/kg | Basis |
| Plant Area | Subsurface Soil | 0-5 ft | 123 | NP, bootstrap | 20,266 | arithmetic mean |
| Grassy Area | Surface Soil | 0-6 in | 312 | NP, bootstrap | 15,916 | arithmetic mean |
| Offsite Natural Gas Facility | Surface Soil | 0-6 in | 28.5 | LN, H-UCL | 1,311 | arithmetic mean |

NP Nonparametric

LN Lognormal

For arsenic, the EPCs were the 95% upper confidence level on the mean (95UCL) concentration. The 95UCL is used instead of the mean or arithmetic average because it is not possible to know the true mean (USEPA, 1992b). The 95UCL is defined as a value that ..."equals or exceeds the true mean 95% of the time" (USEPA, 1992b). As sampling data become more representative of actual site conditions, uncertainties decrease, and the 95UCL approaches the true mean. The 95UCL values were calculated with ProUCL© according to USEPA guidance (USEPA, 2002).

To evaluate lead risks, the arithmetic mean soil lead concentration within the exposure area was used as the EPC to be consistent with USEPA guidance (USEPA, 1994; USEPA, 1996)

3.3 Quantification of Exposure

This section discusses the basis for calculating human intake levels resulting from exposures to COPCs other than lead (in this case arsenic), and describes each input parameter. Human intake levels for lead are discussed in Section 5. Exposure estimates represent the daily dose of a chemical taken into the body, averaged over the appropriate exposure period, expressed in the units of milligram (mg) of chemical per kilogram (kg) of human body weight per day. The primary source for the exposure equations used in the HHRA is the USEPA's "Risk Assessment Guidance for Superfund (RAGS)" (USEPA, 1989). The generalized equation for calculating chemical intakes is shown below:

$$I = \frac{EPC \times CR \times EF \times ED}{BW \times AT}$$

where:

I = Intake, the amount of chemical at the exchange boundary (mg/kg body weight-day),

EPC = Exposure Point Concentration, the chemical concentration contacted over the exposure period at the exposure point (e.g., mg/kg in soil),

CR = Contact Rate, the amount of contaminated medium contacted per unit time or event (e.g., soil ingestion rate (mg/day)),

EF = Exposure Frequency, describes how often exposure occurs (days/year),

ED = Exposure Duration, describes how long exposure occurs (yr),

BW = Body Weight, the average body weight over the exposure period (kg), and

AT = Averaging Time, period over which exposure is averaged (days).

Exposure factors (e.g., contact rate, exposure frequency, exposure duration, body weight) describe a receptor's exposure for a given exposure scenario. The values used for each exposure factor are summarized in Table 3 and discussed in detail below. The exposure factor input values are consistent with current USEPA guidance. Where appropriate, exposure parameters were based on site-specific considerations and professional judgment.

¹ Note that this approach is not used to evaluate lead. Consistent with USEPA guidance, lead exposure is evaluated using a child or adult lead model to estimate blood lead levels.
²⁰³⁰³⁰

Table 3
Summary of Exposure Factor Input Values

| Exposure Area | Onsite Construction | Onsite | Grassy Area | Grassy Area Grounds- | Grassy Area Adolescent | Offsite Gas Facility |
|------------------------------------|------------------------|----------------|-------------|-------------------------|---------------------------|-------------------------|
| Receptor | Worker | Utility Worker | Site Worker | keeper | Trespasser | Worker |
| Exposure Pathway/Exposure Factor | | | | | | |
| Ingestion of Soil | | | | | | |
| Ingestion Rate (mg/kg) | 100 | 100 | 50 | 50 | 50 | 50 |
| Exposure Duration (yr) | 5 | 10 | 25 | 25 | 5 | 25 |
| Exposure Frequency (days/yr) | 50 | 10 | 144 | 50 | 25 | 225 |
| Body Weight (kg) | 70 | 70 | 70 | 70 | 58 | 70 |
| Bioavailability (arsenic) | 8.0 | 8.0 | 0.8 | 0.8 | 0.8 | 8.0 |
| Conversion Factor (kg/mg) | 0.000001 | 0.000001 | 0.000001 | 0.000001 | 0.000001 | 0.000001 |
| Fraction from Contaminated Source | 1 | 1 | 1 | 1 | 1 | 1 |
| Averaging Time (days) - Cancer | 25550 | 25550 | 25550 | 25550 | 25550 | 25550 |
| Averaging Time (days) - Non Cancer | 365 | 3650 | 9125 | 9125 | 1825 | 9125 |
| Dermal Contact with Soil | | | | | | |
| Dermal Absorption Factor (arsenic) | 0.03 | 0.03 | 0.03 | 0.03 | 0.03 | 0.03 |
| Soil Adherence Factor (mg/cm²) | 0.2 | 0.2 | 0.07 | 0.2 | 0.07 | 0.2 |
| Surface Area (cm²/d) | 3300 | 3300 | 3300 | 3300 | 4270 | 3300 |
| Exposure Duration (years) | 5 | 10 | 25 | 25 | 5 | 25 |

Gradient CORPORATION

3.3.1 Ingestion of Soil

For the soil ingestion pathway intake is calculated as:

$$Intake \left(\frac{mg}{kg \cdot day}\right) = \frac{C_{soil} \left(\frac{mg}{kg}\right) \times B \times IR_{soil} \left(\frac{mg}{day}\right) \times FS \times EF \left(\frac{days}{yr}\right) \times ED(yrs) \times 10^{-6} \frac{kg}{mg}}{BW(kg) \times AT(days)}$$

where:

 C_{soil} = Concentration of the chemical in soil (mg/kg)

B = Relative Bioavailability, the relative oral absorption fraction (unitless)

 IR_{soil} = Soil Ingestion Rate (mg/day)

FS = Fraction of Soil from the site (unitless)

EF = Exposure Frequency (days/year)

ED = Exposure Duration (years)

BW = Body Weight (kg)

AT = Averaging Time (days)

Gradient used conservative USEPA-recommended values for each of the input parameters. The basis for each value used is detailed below.

Soil Concentrations (C_{soil}). As summarized in Section 3.2, the 95UCL was used as the EPC.

Relative Bioavailability (B). To accurately quantify potential exposures from ingestion of soil, it is important to consider the amount of a chemical that is solubilized in gastrointestinal fluids and absorbed across the gastrointestinal tract into the bloodstream. A chemical present in soil may be absorbed less completely than the same dose of the chemical administered in toxicity studies used to evaluate safe dose levels. A relative bioavailability estimate for a specific compound represents the absorption fraction from soil (the exposure route of concern) relative to the absorption fraction from food or water (in most toxicity studies, chemical doses are administered in food or water).

It is widely recognized that bioavailability of many metals and organics from soil tends to be considerably lower than bioavailability from food or water. USEPA guidance recognizes the need to make adjustments for the reduced bioavailability of compounds in soil. Specifically, in Appendix A of USEPA's Risk Assessment Guidance for Superfund (USEPA, 1989, pg. A-3), USEPA notes:

"If the medium of exposure in the site exposure assessment differs from the medium of exposure assumed by the toxicity value (e.g., RfD values usually are based on or have been adjusted to reflect exposure via drinking water, while the site medium of concern may be soil), an absorption adjustment may, on occasion, be appropriate. For example, a substance might be more completely absorbed following exposure to contaminated drinking water than following exposure to contaminated food or soil (e.g., if the substance does not desorb from soil in the gastrointestinal tract)."

USEPA Region 10 risk assessment guidance provides default values for the bioavailability of arsenic in soil. Region 10 notes that if the site is a smelter site and its appears likely that the arsenic exists primarily as finely-grained oxides from smelter stack emissions, then a value of 80% relative bioavailability may be assumed. Region 10 notes that this value is supported by a conservative 203030

EBG_RA.doc

interpretation of the scientific literature (USEPA Region 10, 1997). A relative bioavailability of 80% was used for arsenic in this risk assessment.

For lead, the USEPA recommends an oral absorption factor for adults of 0.12 for ingestion of lead in soil, based on 20% absorption of soluble lead, and a relative bioavailability of 60% for lead in soil (i.e., $0.12 = 0.2 \times 0.6$) (USEPA, 1996). Gradient used the recommended USEPA absorption factor of 0.12 to evaluate ingestion of lead contaminated soil for adult receptors.

Soil Ingestion Rate (IR_{soil}). A daily soil and dust ingestion rate of 50 mg/day was used for the adolescent trespasser and the following adult receptors: site worker, groundskeeper, and offsite gas facility worker. USEPA considers this value to be a reasonable central estimate of adult soil ingestion and notes that although this value is highly uncertain, "a recommendation for an upper percentile value would be inappropriate" (USEPA, 1997a). A daily soil and dust ingestion rate of 100 mg/day was used for the onsite construction worker and the onsite utility worker, as these receptors are assumed to have more intensive contact with soil than the other adult receptors.

Fraction of Soil From the Site (FS). For all receptors, it was assumed that 100% of the individual's daily soil exposure occurred at the site. This assumption is likely to overestimate exposure to contaminated soil for workers and trespassers because workers are assumed to be at the site for only 8 hours per day, and trespassers are likely present less than 2 hours per visit.

Exposure Frequency (EF) and Exposure Duration (ED). The exposure frequency and duration used for each receptor are discussed in Section 3.1.1 to 3.1.3. For the site worker, groundskeeper, and offsite gas worker, the exposure duration is 25 years. This is the 95th percentile duration that an individual stays at any one workplace (USEPA, 1991). Hence, this assumption overestimates exposures for most workers, because the median occupational tenure of the working population has been estimated to be 6.6 years (USEPA, 1997a).

Body Weight (BW). Although the average U.S. adult body weight in the current Exposure Factors Handbook (USEPA, 1997a) is 71.8 kg, a mean adult body weight of 70 kg (USEPA, 1991) was used in the HHRA, so that the body weight would be consistent with that used in deriving the toxicity factors. Average body weight for the adolescent trespasser (13-18 year old) was calculated from data in USEPA's Exposure Factors Handbook and used in the HHRA (USEPA, 1997a).

Averaging Time (AT). For non-cancer risks, the averaging time was equal to the exposure duration multiplied by 365 days/year. For cancer risks, exposures were averaged over a 70-year average lifetime (USEPA, 1991). Although the current life expectancy for men and women in the U.S. is 76.7 years (USEPA, 1997a), a value of 70 years (25,550 days) was used to be consistent with the value used in deriving the toxicity factors.

3.3.2 Dermal Contact with Surface Soil

For dermal exposure to contaminants in soil, a dermal intake (the amount absorbed into the body) is calculated as (USEPA, 1999):

$$Intake \left(\frac{mg}{kg \cdot day}\right) = \frac{C_{soil}\left(\frac{mg}{kg}\right) \times DA \times AF\left(\frac{mg}{cm^{2}}\right) \times SA\left(\frac{cm^{2}}{event}\right) \times EF\left(\frac{events}{yr}\right) \times ED(yrs) \times 10^{-6} \frac{kg}{mg}}{BW(kg) \times AT(days)}$$

where:

 C_{soil} = Concentration of the chemical in soil (mg/kg),

DA = Dermal Absorption factor (unitless)

AF = Soil/skin Adherence Factor (mg/cm²),

SA = Skin surface Area exposed (cm²/exposure event),

EF = Exposure Frequency (exposure events/year),

ED = Exposure Duration (years),

BW = Body Weight (kg), and

AT = Averaging Time (days).

There are three parameters in this equation that are different from those discussed in the previous section (Section 3.3.1). Only those parameters unique to the dermal exposure equation, dermal absorption fraction (DA), the soil adherence factor (AF), and the skin surface area (SA), are discussed in this section.

Note that since absorbed doses are used for the dermal pathway, the toxicity criteria are adjusted so they apply to absorbed doses. This adjustment is discussed in more detail in the toxicity section (Section 4).

Dermal Absorption Fraction (DA). The dermal absorption fraction represents the amount of a chemical in contact with skin that is absorbed through the skin and into the bloodstream. The dermal absorption fraction for arsenic (0.03) was obtained from USEPA's dermal risk assessment guidance (USEPA, 1999; Table 3.4).

Soil to Skin Adherence Factor (AF). The adherence factor relates the amount of soil that adheres to the skin per unit of surface area (USEPA, 1999). Adherence factors vary depending on the properties of the soil, the part of the body, and the type of activity. Gradient used the 50th percentile weighted adherence factors from USEPA's dermal risk assessment guidance (USEPA, 2001). The AF for utility workers (0.2 mg/cm²) was used for the construction worker, utility worker, groundskeeper, and offsite gas facility worker. EPA's recommended AF for the residential adult (0.07 mg/cm²) was used for the future site worker and the adolescent trespasser.

Skin Surface Area Exposed (SA). This parameter reflects the amount of skin that is available for exposure to soil. The skin surface areas used in the HHRA were 3300 cm² for the construction worker, utility worker, site worker, groundskeeper, and offsite gas facility worker, based on the face, hands, and forearms; and 4270 cm² for the trespasser, based on the face, hands, forearms, and lower legs. Surface areas were calculated using USEPA's Exposure Factors Handbook (USEPA, 1997).

4 Toxicity Assessment

4.1 Overview of Toxicity Values

Gradient has evaluated potential cancer and non-cancer risks from exposure to arsenic using dose-response relationships for carcinogenicity (oral Cancer Slope Factors) and systemic toxicity (oral Reference Doses). Lead toxicity is discussed separately in Section 4.2. The primary source of toxicity values was the USEPA's Integrated Risk Information System (IRIS) (USEPA, 2004). Toxicity values in IRIS undergo a rigorous peer review process and are generally considered to be of high quality. The toxicity factors used in the HHRA are summarized in Table 4-1.

Table 4
Toxicity Factors

| Compound | RfD _{oral} (mg/kg- day) | Critical Effect | RfD Source | Uncertainty Factor | Oral Absorption | RfD _{dermal} (mg/kg- day) | CSF _{oral} (mg/kg- day) | CSF _{dermal} (mg/kg- day) |
|----------|--|---|---------------|-----------------------|--------------------|--|--|--|
| Arsenic | 0.0003 | Hyperpigmentation, keratosis and possible vascular complications | IRIS | 3 | 95% | 0.0003 | 1.5 | 1.5 |

4.1.1 Oral Reference Doses (RfD_{oral})

An RfD is an estimate of daily exposure that a sensitive population can experience over a lifetime with a negligible risk of systemic health effects. The USEPA derives RfDs by first identifying the highest dose level that does not cause observable adverse effects (i.e., the No Observed-Adverse Effect Level, or NOAEL; USEPA, 1993). If a NOAEL was not identified, a Lowest Observed Adverse Effect-Level, or LOAEL, may be used. This dose level is then divided by uncertainty factors to calculate an RfD. An uncertainty factor of 100 is often used, to account for interspecies differences (if animal studies were used) and sensitive human subpopulations (e.g., children and the elderly; USEPA, 1993). Additional uncertainty factors may be used, depending on the quality of the toxicological data.

4.1.2 Oral Cancer Slope Factors (CSF_{oral})

The CSF is an upper bound estimate of carcinogenic potency used to calculate risk from exposure to carcinogens, by relating estimates of lifetime average chemical intake to the incremental risk of an individual developing cancer over their lifetime (USEPA, 1992c). The CSFs recommended by the USEPA are conservative upper bound estimates, which means that the USEPA is reasonably confident that the "true" cancer risk does not exceed the estimated risk calculated using the CSF, and may be as low as zero.

4.1.3 Dermal Reference Doses (RfD_{dermal})

There are no USEPA-derived toxicity values based specifically on toxicity studies involving dermal exposures. In the absence of dermal-specific RfDs, oral toxicity factors are used, assuming that

11

EBG_RA.doc

once a chemical is absorbed into the blood stream, the health effects are similar regardless of whether the route of exposure is oral or dermal. However, since oral toxicity criteria are based on the amount of a chemical *administered* per unit time and body weight (chemical intake), they need to be adjusted to be applicable to *absorbed* doses (dermal exposures are expressed as absorbed intake levels) (USEPA, 1989; 1992a; 1999).

Since most RfDs are based on studies where a chemical is administered in food or water, this adjustment is made using the oral absorption efficiency for that chemical. If oral absorption is very high (almost 100%), then the absorbed dose is virtually the same as the administered dose, and no adjustment of the toxicity factor is necessary. If oral absorption is very low (e.g., 5%), the absorbed dose is much smaller than the administered dose, and an adjustment of the toxicity criteria is necessary. For any given chemical, the USEPA recommends adjusting the oral toxicity factor for use in evaluating dermal risks only when the oral absorption for that chemical is less than 50%, to "obviate the need to make comparatively small adjustments in the toxicity value that would otherwise impart on the process a level of accuracy that is not supported by the scientific literature" (USEPA, 1999).

For non-cancer effects, this adjustment is made by multiplying the oral RfD (for applied doses) by the oral absorption efficiency (i.e., $RfD_{oral} \times Abs_{oral} = RfD_{dermal}$). For arsenic, the oral absorption efficiency is 95%, therefore no adjustment is necessary and the RfD_{dermal} is the same as the RfD_{oral} (Table 4).

4.1.4 Dermal Cancer Slope Factors (CSF_{dermal})

There are no USEPA-derived toxicity values specifically for cancer studies involving dermal exposures. In the absence of dermal-specific CSFs, oral CSFs are used, assuming that once a chemical is absorbed into the blood stream, the carcinogenic effect is similar regardless of whether the route of exposure is oral or dermal. However, since oral CSFs are based on the amount of a chemical administered per unit time and body weight (chemical intake), they need to be adjusted to be applicable to absorbed doses (dermal exposures are expressed as absorbed intake levels) (USEPA, 1989; 1992a; 1999). For any given chemical, the USEPA recommends adjusting the oral CSF for use in evaluating dermal risks only when the oral absorption for that chemical is less than 50%, to "obviate the need to make comparatively small adjustments in the toxicity value that would otherwise impart on the process a level of accuracy that is not supported by the scientific literature" (USEPA, 1999).

For cancer, this adjustment is made by dividing the oral CSF (for applied doses) by the oral absorption efficiency (i.e., CSF_{oral} / $Abs_{oral} = CSF_{dermal}$), if the oral absorption efficiency is less than 50%. For arsenic, this value is 95%, therefore the CSF_{dermal} is the same as the CSF_{oral} (Table 4).

4.2 Toxicity Values for COPCs

The basis of the arsenic toxicity values is described in this section and summarized in Table 4. Lead toxicity is also discussed in this section because of the unique way exposure and risk are evaluated for this metal.

4.2.1 Arsenic

The toxicity criteria for arsenic were obtained from the USEPA IRIS database (USEPA, 2000). The derivation of each of these values, and the scientific uncertainties concerning arsenic toxicity, are discussed below.

4.2.1.1 Arsenic RfD_{oral}

USEPA cites an RfD_{oral} for arsenic of 0.0003 mg/kg-day (USEPA, 2000). The arsenic RfD_{oral} is based on increased incidence of hyperpigmentation, keratosis and possible vascular complications in a study of a large population (over 40,000 people) in Taiwan with chronic exposure to arsenic in drinking water and food (Tseng, 1977; Tseng *et al.*, 1968). The USEPA characterized a NOAEL of 0.0008 mg/kg/day for skin lesions in the Tseng study, based on the drinking water concentration in the NOAEL group (0.009 mg/L), an assumed drinking water ingestion rate of 4.5 L, daily arsenic intake from sweet potatoes and rice of 0.002 mg/day, and an average Taiwanese body weight of 55 kg ((0.009 mg/L × 4.5 L/day) + 0.002 mg/day / 55 kg) (Abernathy *et al.*, 1989). An uncertainty factor of 3 (based on the lack of reproductive toxicity data and uncertainty regarding toxicity in sensitive individuals) was applied to the NOAEL to derive an RfD of 0.0003 mg/kg/day (0.0008/3). Overall, the USEPA has "medium" confidence in the study, "medium" confidence in the database (due to poor characterization of the dose levels in the Tseng and other supporting studies), and "medium" confidence in the RfD_{oral} for arsenic. It is noted in the arsenic IRIS file that a clear consensus does not exist among USEPA scientists regarding arsenic systemic toxicity (USEPA, 2000).

4.2.1.2 Arsenic CSF_{oral}

USEPA concluded that arsenic is a "human carcinogen," a weight-of-evidence classification for carcinogenicity of "A" (USEPA, 2000). This classification is based on sufficient evidence of carcinogenicity in human populations. Lung cancer has been associated with inhalation of arsenic, and skin, bladder, and possibly other internal cancers have been associated with ingestion of arsenic in drinking water.

In IRIS, the USEPA recommends a CSF_{oral} value for arsenic of 1.5 (mg/kg/day)⁻¹ (USEPA, 2000). This value is based on skin cancer incidence rates in the same Taiwanese study used as the basis for the RfD_{oral} value (Tseng, 1977; Tseng *et al.*, 1968). This value was calculated using a multistage model, assuming a drinking water ingestion rate of 3.5 L/day for Taiwanese males and 2 L/day for Taiwanese females, an average Taiwanese body weight of 55 kg, and an average U.S. body weight of 70 kg.

There is currently considerable debate among the scientific community regarding the arsenic CSF_{oral}. Many researchers believe that the current value of 1.5 (mg/kg/day)⁻¹ may overestimate cancer risks for U.S. populations (see, for example, Slayton *et al.*, 1996; Chappell *et al.*, 1997).

4.2.1.3 Arsenic RfD_{derm} and CSF_{derm}

In general, for dermal exposures (expressed as absorbed intake levels), the RfD_{oral} and CSF_{oral} are adjusted to be applicable to absorbed doses (USEPA, 1989; 1992a). This adjustment is made assuming that once a chemical is absorbed into the blood stream, the health effects are similar regardless of whether the route of exposure is oral or dermal. However, since oral absorption for arsenic is about 95% (USEPA, 1999), and the USEPA recommends adjusting dermal toxicity factors only when oral absorption is less than 50%, no adjustment was made for arsenic.

203030

4.2.2 Lead

The ingestion of lead at certain levels can result in significant health effects, particularly among children. Epidemiological investigators have reported a correlation between blood lead levels (BLLs) in children and adverse health effects. High levels of lead intake can cause kidney damage, convulsions, coma, and even death (ATSDR, 1999). However, health effects resulting from lower levels of lead exposure are more common, and are related to cognitive and neuro-behavior impacts, including the impairment of intellectual performance.

The USEPA has not established any toxicity criteria (RfD, CSF) for lead (USEPA, 2004); instead, lead risks are evaluated by modeling blood lead levels. Lead risks in adults were evaluated using USEPA's Adult Lead Model (USEPA, 2003). This model is discussed in more detail in Section 5.4.

The USEPA has assigned lead a Weight-of-Evidence Classification for human carcinogenicity of "B2", a "probable human carcinogen," based on sufficient animal evidence but inadequate human evidence (USEPA, 2004). Even though the weight of evidence for lead carcinogenicity is B2, the USEPA does not evaluate lead cancer risk using a CSF, having concluded that neurological effects in young children are the most relevant endpoint.

5 Risk Characterization

In this section, cancer and non-cancer health risks are estimated by combining the information from Sections 2 through 4. The calculations used to estimate cancer and noncancer risks are presented in Sections 5.1 and 5.2, respectively. Section 5.3 discusses the calculated cancer and noncancer risks for each exposure area. Section 5.4 presents the lead risks by exposure area. Section 5.5 provides a qualitative discussion of the most significant sources of uncertainty in the risk estimates.

5.1 Calculation of Cancer Risks

Excess lifetime cancer risks are characterized as the incremental probability that an individual will develop cancer during his or her lifetime due to chemical exposure to constituents at the site under the specific exposure scenarios evaluated. The term "incremental" implies the risk above the background cancer risk experienced by all individuals in the course of daily life. According to Greenlee *et al.* (2001), the lifetime probability of developing cancer (*i.e.*, background cancer risk) is approximately 0.435 in men, and 0.383 in women. Cancer risks are expressed as a unitless probability (*e.g.*, one in a million, or 10^{-6}) of an individual developing cancer over a lifetime, above background risk, as a result of exposure to impacted environmental media at a site.

Excess (incremental) cancer risks for all of the exposure pathways (oral, dermal, and inhalation) are calculated using intake estimates (lifetime average daily doses, calculated in Section 3 as part of the exposure assessment) and CSFs (summarized as part of the toxicity assessment in Section 4) as follows (USEPA, 1989):

$$CancerRisk = Intake \left(\frac{mg}{kg \cdot day}\right) \times CSF \left(\frac{mg}{kg \cdot day}\right)^{-1}$$

For ingestion pathways, oral intake estimates (expressed as applied or administered dose levels) are multiplied by the oral CSF (applicable to applied/administered doses). Similarly, for inhalation pathways, inhalation intake estimates (also expressed as applied or administered dose levels) are multiplied by the inhalation CSF (applicable to applied/administered doses). For dermal exposures, dermal intake estimates (expressed as an absorbed dose level) are multiplied by an adjusted oral CSF (adjusted to apply to absorbed doses) (USEPA, 1999). The total cancer risk for each receptor is the sum of the risks across all of the exposure pathways.

5.2 Calculation of Noncancer Risks

Risks from non-carcinogenic health effects are expressed as hazard quotients rather than as probabilities. A hazard quotient compares the calculated exposure (average daily doses, calculated as part of the exposure assessment in Section 3) to acceptable reference exposures derived by the USEPA (e.g., RfDs, summarized as part of the toxicity assessment in Section 4). The hazard quotient is calculated from the RfD as follows (USEPA, 1989):

$$Hazard Quotient = \frac{Intake \left(\frac{mg}{kg \cdot day}\right)}{RfD \left(\frac{mg}{kg \cdot day}\right)}$$

For the ingestion exposure route an oral intake estimate (expressed as applied or administered dose) is divided by the oral RfD (applicable to applied/administered dose). Similarly, for the inhalation exposure route an inhalation intake estimate (also expressed as applied or administered dose) is divided by the inhalation RfD (applicable to applied/administered dose). For dermal exposure, a dermal intake estimate (expressed as an absorbed dose) is divided by an adjusted oral RfD (adjusted to apply to absorbed dose).

Hazard indices are calculated for each receptor and exposure pathway, according to USEPA guidance (1989). A hazard index greater than 1.0 is considered to represent a significant health risk. Because a hazard quotient is simply a ratio of site exposures to reference exposure levels (e.g., RfDs, RfCs, etc.), hazard indices do not represent the probability that an adverse health effect could occur. They simply indicate whether an estimated exposure for an individual presents a significant noncancer health risk, based on the USEPA's recommended reference dose.

5.3 Estimated Cancer and Noncancer Risks

The estimated cancer and noncancer risks for arsenic are discussed below by exposure area. Lead risks are discussed separately in Section 5.4. Cancer risks are summarized in Table 5. The total cancer risk for each receptor is the sum of the risks over all exposure routes and all exposure periods. Noncancer risks are summarized in Table 5. The total noncancer risk for each receptor is the sum of the risks over all exposure routes. The detailed risk calculation tables in Appendix A present the arsenic risks calculated for each receptor and exposure pathway. The percent contribution of each exposure pathway to the total risk is also shown.

5.3.1 Main Facility Area

In the main facility area onsite, we evaluated a construction worker and a utility worker for exposure to arsenic in subsurface soil *via* incidental ingestion and dermal contact.

The total excess lifetime cancer risk is 3×10^{-6} for the construction worker, and 1×10^{-6} for the utility worker. These risk estimates are within USEPA's target risk range of 1×10^{-6} to 1×10^{-4} , indicating that exposure to arsenic in subsurface soil in the main facility area does not present a significant cancer risk for the construction or utility worker.

The total hazard index (HI) is 0.1 for the construction worker, and 0.02 for the utility worker. These values are well below a HI of 1.0, therefore, exposure to arsenic in subsurface soil in the main facility area does not present a significant noncancer risk for the construction or utility worker.

5.3.2 Grassy Areas

In the grassy areas located north, south, and east of the main facility, we evaluated a future site worker, a groundskeeper, and an adolescent trespasser, for exposure to arsenic in surface soil *via* incidental ingestion and dermal contact.

The total excess lifetime cancer risks are 4×10^{-5} for the future site worker, 2×10^{-5} for the groundskeeper, and 2×10^{-6} for the adolescent trespasser. These risk estimates are within USEPA's target risk range of 1×10^{-6} to 1×10^{-4} , indicating that exposure to arsenic in surface soil in the grassy area does not present a significant cancer risk for these receptors.

The total hazard index (HI) is 0.3 for the future site worker, and 0.1 for the groundskeeper and adolescent trespasser. These values are well below a HI of 1.0, therefore, exposure to arsenic in surface soil in the grassy area around the facility does not present a significant noncancer risk for these receptors.

5.3.3 Offsite Natural Gas Facility

At the off-site natural gas facility to the west of the RMC property, we evaluated a facility worker exposed to arsenic in surface soil *via* ingestion and dermal contact.

The total excess lifetime cancer risk is 8×10^{-6} for the gas facility worker. This risk estimate is within USEPA's target risk range of 1×10^{-6} to 1×10^{-4} , indicating that exposure to arsenic in surface soil at the natural gas facility area does not present a significant cancer risk for the worker.

The total hazard index (HI) is 0.1 for the gas facility worker. This value is well below a HI of 1.0, therefore, exposure to arsenic in surface soil at the gas facility does not present a significant noncancer risk for the worker.

Table 5
Summary of Cancer and Noncancer Risks

| Exposure Area | Medium | Receptor | Total Excess Lifetime Cancer Risk | Total Hazard Index |
|----------------------------------|-----------------|-----------------------|---|-----------------------|
| Main Plant Area | Subsurface soil | Construction Worker | 3E-06 | 0.1 |
| | Subsulface son | Utility Worker | 1E-06 | 0.02 |
| | · | Groundskeeper | 2E-05 | 0.1 |
| Grassy Areas | Surface soil | Adolescent Trespasser | 2E-06 | 0.1 |
| | | Future Site Worker | 4E-05 | 0.3 |
| Off Site Natural Gas Facility | Surface soil | Adult Worker | 8E-06 | 0.1 |

5.4 Lead Risk Assessment

5.4.1 Adult Lead Model

Blood lead levels (BLLs) in adolescents and adults are assessed using USEPA's Adult Lead Model (ALM) (USEPA, 1996). USEPA's Adult Blood Lead Model predicts a median BLL estimate for an adult as a function of the baseline BLL plus an increment that is attributable to exposure to site soil. This increment is a function of the biokinetic slope factor, the concentration of lead in soil, the soil ingestion rate, the fraction of lead in soil that is absorbed, and the exposure frequency. EPA has selected a target BLL for an adult female, in order to protect a developing fetus such that no more than 5% of fetuses would be expected to have BLLs exceeding $10 \,\mu g/dL$.

The basic form of the equation for the ALM is as follows:

$$BLL_{adult} = PbB + \frac{\left(EF \times AF \times PbS \times IR \times BKSF\right)}{AT}$$

The input values used in the model are summarized in Table 6 and described below. First, an average baseline lead concentration in blood (PbB_{base}) for adults is identified to account for continuing exposure to background levels of lead in food, soil, and dust, and pre-existing body burdens due to prior lead exposures. Baseline BLLs were obtained from the most recent National Health and Nutrition Examination Survey, from 1999-2000 (NHANES 2000) (U.S. Public Health Service, 2004). For adults we used the geometric mean (GM) and geometric standard deviation (GSD) BLLs for women of childbearing age (age 20-49). For the adolescent trespasser, we used the GM and GSD BLLs for males and females combined, for 13-18 year olds. To this baseline, the model adds the incremental increase in blood lead due to the lead source of interest (in this case, exposure to lead *via* ingestion of soil and dust).

The concentration of lead in soil (PbS) is the mean lead concentration in each exposure area. Lead uptake is calculated by multiplying the concentration of lead in soil by the soil/dust ingestion rate (IR) and the absorption fraction (AF) for lead in soil and dust. The AF is the amount of lead that is absorbed into the bloodstream from the gastrointestinal tract. The exposure frequency (EF) varies by receptor and exposure area. The EFs used for each receptor are presented in Table 3. The averaging time (AT) for chronic exposure to lead in soil is assumed to be one year (i.e., 365 days). The biokinetic slope factor (BKSF) relates the incremental lead uptake into the body to an incremental increase in blood lead level in adults. USEPA's default value of 0.4 was used for the BKSF.

Table 6
Adult Lead Model Input Values

| Term | Definition | Value |
|------------------|--|--------------------------------|
| PbB ₀ | Geomean baseline BLL (µg/dL) for Adult females | |
| | (age 20-49 yr) | 1.2 |
| GSD | Geometric standard deviation for Adult females | 1.8 |
| PbB_0 | Geomean baseline BLL ($\mu g/dL$) for 13-18 yr old males and females | 1.1 |
| GSD | Geometric standard deviation for 13-18 yr old males and females | 1.8 |
| EF | Exposure Frequency (i.e., number of days during the averaging time an individual is exposed to the lead source being evaluated (days)) | Receptor-specific |
| AT | Averaging Time (days) | 365 |
| PbS | Soil/dust lead concentration (μg/g) | Area-Specific |
| IR | Soil/dust Ingestion Rate (g/day) | Receptor-specific 0.05 or 0.10 |
| AF | Fraction of ingested lead absorbed into the blood stream (dimensionless) | 0.12 |
| BKSF | Biokinetic Slope Factor (change in blood lead per μg change in daily lead uptake) (μg/dL per μg/day) | 0.4 |

Total BLLs for adults are predicted by adding the estimated incremental increase in blood lead to the average baseline BLL. A geometric standard deviation (GSD) appropriate for adults is used to estimate the probable range of BLLs around the predicted geometric mean adult BLL from the model. For this evaluation, we used the actual GSDs for the BLLs obtained from the NHANES-2000 database.

BLLs estimated using the ALM are evaluated based on a comparison to the USEPA risk management criterion for lead. Specifically, the health protection goal of the USEPA Office of Solid Waste and Emergency Response is to "limit exposure to soil lead levels such that a typical (or hypothetical) child or group of similarly exposed children would have an estimated risk of no more than 5% of exceeding a blood lead of 10 μ g/dL" (USEPA, 1998a). The Centers for Disease Control (CDC) recommend that "the goal of all lead poisoning prevention activities should be to reduce children's BLLs below 10 μ g/dL" (CDC, 1991). Based on a goal of keeping the BLL in children at or below 10 μ g/dL, the BLL for women of child-bearing age should not exceed 11.1 μ g/dL, because the fetal BLL is approximately 90% of the maternal BLL (*i.e.*, 90% of 11.1 μ g/dL is 10 μ g/dL). A BLL goal of 10 μ g/dL was used for the adolescent trespasser.

The adult lead modeling results for all receptors, along with the input values, the predicted BLLs, and the probability of exceeding the target BLL, are presented in Table 7. The adult lead modeling results are discussed below by exposure area. The dermal exposure route for lead in soil was not evaluated because this exposure route is typically insignificant when compared to ingestion. The ALM makes no provision for assessing dermal exposures.

Table 7 Summary of Lead Risks and Cleanup Goals

| | Soil E | xposure Depth | 0-5 ft | 0-5 ft | 0-6" | 0-6" | 0-6" | 0-6" |
|----------------------------|--|---------------------|------------------------|----------------|--------------------|-------------------|--------|-------------------------|
| | | | | Values for | r Non-Resident | tial Exposure Sce | nario | |
| Exposure | | | On | site | Grassy Area | | | Offsite Gas Facility |
| Variable | Description of Exposure Variable | Units | Construction Worker | Utility Worker | Grounds- keeper | Trespasser | Worker | Worker |
| PbS | Soil lead concentration | ug/g or ppm | 20,266 | 20,266 | 15,916 | 15,916 | 15,916 | 1311 |
| R _{fctsUmsternal} | Fetal/maternal PbB ratio | _ | 0.9 | 0.9 | 0.9 | 0.9 | 0.9 | 0.9 |
| BKSF | Biokinetic Slope Factor | ug/dL per ug/day | 0.4 | 0.4 | 0.4 | 0.4 | 0.4 | 0.4 |
| GSD _i | Geometric standard deviation PbB | | 1.8 | 1.8 | 1.8 | 1.8 | 1.8 | 1.8 |
| PbB ₀ | Baseline PbB | ug/dL | 1.2 | 1.2 | 1.2 | 1.1 | 1.2 | 1.2 |
| IR _s | Soil ingestion rate (including soil-derived indoor dust) | g/day | 0.100 | 0.100 | 0.050 | 0.050 | 0.050 | 0.050 |
| IR _{S+D} | Total ingestion rate of outdoor soil and indoor dust | g/day | | | - | | | |
| W _s | Weighting factor; fraction of IR _{S+D} ingested as outdoor soil | | | | | | | |
| K _{SD} | Mass fraction of soil in dust | | | | | | - | |
| AF _{s, D} | Absorption fraction (same for soil and dust) | | 0.12 | 0.12 | 0.12 | 0.12 | 0.12 | 0.12 |
| EF _{s, D} | Exposure frequency (same for soil and dust) | days/yr | 50 | 10 | 50 | 25 | 144 | 225 |
| AT _{s. D} | Averaging time (same for soil and dust) | days/yr | 365 | 365 | 365 | 365 | 365 | 365 |
| PbB _{adult} | PbB of adult worker, geometric mean | ug/dL | 15 | 3.9 | 6.4 | 3.7 | 16 | 3.1 |
| PbB _{feral, 0.95} | 95th percentile PbB among fetuses of adult workers | ug/dL | 34 | 9.1 | 15 | 8.8 | 39 | 7.4 |
| PbB, | Target PbB level of concern (e.g., 10 ug/dL) | ug/dL | 10.0 | 10.0 | 10.0 | 10.0 | 10.0 | 10.0 |
| $P(PbB_{fetal} > PbB_{t})$ | Probability that fetal PbB > PbB,, assuming lognormal distri | % | 68% | 4% | 18% | 3% | 74% | 2% |
| PRG | Preliminary Remediation Goal (PRG) | ppm | 4601 | 23003 | 9201 | 19011 | 3195 | 2045 |
| | Clean Fill (assumed) | ppm | 50 | | | | 50 | |

Source: U.S. EPA (1996). Recommendations of the Technical Review Workgroup for Lead for an Interim Approach to Assessing Risks Associated with Adult Exposures to Lead in Soil

5.4.2 Main Facility Area

In the main facility area, lead risks were evaluated for a construction worker and a utility worker exposed to subsurface soil (0-5 ft). The predicted 95th percentile fetal BLLs are 34 μ g/dL for the construction worker and 9.1 μ g/dL for the utility worker. The predicted BLL for the fetus of the construction worker exceeds the BLL goal of 10 μ g/dL, thus lead in subsurface soil poses an unacceptable risk in the main facility area. The exceedance is due to the elevated subsurface soil EPC of 20,266 mg/kg, which represents the average concentration for depths of 0-5 ft across the site. The utility worker has a much lower exposure frequency than the construction worker, thus his predicted 95th percentile BLL is below the adult 95th percentile goal of 10 μ g/dL.

5.4.3 Grassy Areas

In the grassy area, lead risks were evaluated for a future site worker, a groundskeeper, and an adolescent trespasser exposed to surface soil. The predicted 95th percentile fetal BLLs are 15 μ g/dL for the groundskeeper, 8.8 μ g/dL for the trespasser, and 39 μ g/dL for the future site worker. The predicted fetal BLLs for the groundskeeper and the future site worker exceed the BLL goal of 10 μ g/dL, thus lead in surface soil poses an unacceptable risk in this exposure area. This exceedance is due to the elevated surface soil lead concentration in the grassy area (15,916 mg/kg).

5.4.4 Offsite Natural Gas Facility

At the offsite natural gas facility, lead risks were evaluated for an offsite worker exposed to surface soil. The predicted 95th percentile fetal BLL is 7.4 μ g/dL for the offsite worker. The predicted BLL is below the goal of 10 μ g/dL, therefore, lead does not pose a significant risk to a worker exposed to surface soil in this exposure area.

5.5 Uncertainty Analysis

The process of evaluating human health risks involves multiple steps. Inherent in each step of the process are uncertainties that ultimately affect the final risk estimates. Uncertainties may exist in numerous areas, including sample collection, laboratory analysis, derivation of toxicity values, and estimation of potential site exposures. These uncertainties may result in either an over- or underestimation of risks. However, for this risk assessment, where uncertainties existed, Gradient took a conservative approach in regards to parameters, assumptions, and methodologies, so as to overestimate potential exposures and risks. The most important contributors to uncertainty in this risk assessment are discussed below.

5.5.1 Uncertainties in Exposure Assessment

Soil Ingestion Rate. The adult soil ingestion rate used in the risk calculations and in the ALM was the USEPA default value of 0.05 g/day. However, a survey of recent literature suggests that the average soil and dust ingestion rate value for adults is closer to 0.02 g/day (Bowers et al., 1994).

Lead Absorption Fraction. A lead absorption fraction used in the ALM was USEPA's default value of 0.12. This value is based on 20% absorption of lead from water, and 60% relative bioavailability of lead from soil $(0.20 \times 0.60 = 0.12)$. The 20% absorption of lead from water is an upper-end value $\frac{203030}{2000}$

based on consumption on an empty stomach. This is a conservative assumption that may overestimate risk. O'Flaherty (1993) suggests that a value of 8% may be a more appropriate absorption value for food and water in adults. This value assumes that people consume food at average mealtimes throughout the day, therefore the lead absorption rate is slower due to the presence of food in the stomach. If we use an adult soil ingestion rate of 0.02 g/day, combined with a lead absorption fraction of 8% (or for soil, $0.08 \times 0.6 = 0.048$), we find that the lead risks calculated for adult receptors could be on the order of 60-70% lower than those presented here. Thus the adult lead risks presented in this report are likely conservative overestimates.

Fraction from site. Each receptor's daily soil exposure was assumed to be solely from impacted soil within the exposure area. This is a conservative assumption, since it is expected that workers would be at the site for only 8 hours a day, and would be exposed to soil and dust from other sources during the remaining part of each day (e.g., from home). For instance, in the grassy area, the exposure is likely overestimated for the future site worker, since we assumed he would obtain 100% of this daily soil ingestion during the hour or so that he visits the grassy area at lunchtime.

Exposure Duration. Gradient assumed an upper bound (95th percentile) exposure duration of 25 years for the future site worker, groundskeeper, and offsite gas facility worker (USEPA, 1991). This assumption is conservative and is likely to result in an overestimate of exposure and risk for most workers, since many workers do not remain at the same job for 25 years.

5.5.2 Uncertainties in Arsenic Risk Assessment

Risk management decisions for arsenic are confounded by the unusual nature of natural arsenic background risks, which for both food and water yield cancer risks of 10⁻⁴ or higher, and because of the substantial uncertainty associated with the arsenic cancer slope factor. This section describes some of the unique uncertainties associated with arsenic. In general, the assumptions we have used tend to overestimate arsenic risks.

5.5.2.1 Background Levels of Arsenic in Food, Water, Air, and Soil

Humans are exposed to low levels of arsenic in food, water, air, and soil (ATSDR, 2000). Food is typically the largest source of arsenic exposure, with dietary exposure accounting for about 70% of the daily intake of inorganic arsenic (Borum and Abernathy, 1994). The U.S. EPA estimates that the U.S. population ingests approximately 18 µg of inorganic arsenic every day from food (USEPA 1988). This translates into a 4×10^{-4} cancer risk estimate based on continuous lifetime exposure, and EPA's current assessment of the carcinogenic potential of arsenic.

In the U.S., the average background level of arsenic in drinking water is approximately 2 μ g/L (ATSDR, 2000). The recent U.S. EPA rule allows a permissible level or maximum contaminant level (MCL) of 10 μ g/L arsenic in drinking water (USEPA 2001b), a 5-fold lower value than the prior MCL of 50 μ g/L. The rule allows community and non-transient, non-community water systems 5 years to attain compliance with the new MCL. Assuming the average background level and an ingestion rate of 2 L drinking water per day, an adult would ingest 4 μ g inorganic arsenic per day. At the new MCL of 10 μ g/L, an adult would ingest 20 μ g inorganic arsenic per day, while at the old MCL of 50 μ g/L, an adult would ingest 100 μ g inorganic arsenic per day. These values translate into a range of cancer risk estimates between $9x10^{-5}$ and $2x10^{-3}$ based on continuous lifetime exposure, and EPA's current assessment of the carcinogenic potential of arsenic. EPA currently estimates that approximately 11

million people in the U.S. are served by community water systems with arsenic levels above the revised MCL. These people therefore have a cancer risk from water alone above $4x10^{-4}$.

The mean levels of arsenic in ambient air range from less than 1 to 3 ng/m³ in rural areas and from 20 to 30 ng/m³ in urban areas (ATSDR, 2000). Assuming an inhalation rate of 20 m³/day, an adult would breathe in less than 0.02 to 0.06 µg inorganic arsenic per day in rural areas, and 0.4 to 0.6 µg in urban areas. Arsenic levels could be higher in urban areas due to emissions from coal-fired power plants. However, the maximum concentrations measured in a 24-hour period are generally below 100 ng/m³ (ATSDR, 2000). These background values translate into a range of cancer risk estimates between 4x10⁻⁷ and 1x10⁻⁵.

Background arsenic levels in soil in Indiana range from 3.6 to 15 mg/kg, with an average concentration of 7.5 mg/kg (Dragun and Chiasson, 1991).

Total cancer risk from a combination of background exposures to arsenic in food, water, air, and soil may be as high as between 10⁻⁴ and 10⁻³ for a substantial portion of the U.S. population.

5.5.2.2 Body Burdens of Arsenic

Soil arsenic has a modest impact on body burden, as evidenced by urinary arsenic levels. Although elevated urinary arsenic levels were reported to be associated with very high soil arsenic levels near copper smelters (Baker et al., 1977; Binder et al., 1987), several studies consistently demonstrated that very low urinary arsenic levels were produced from soil arsenic concentrations below 200 mg/kg. In addition, the Anaconda, MT study demonstrated that urinary arsenic levels were unaffected by soil arsenic levels as high as 500 mg/kg. This observation occurs in part because of the small impact of soil arsenic relative to the impact of background levels of arsenic in food and water.

5.5.2.3 Bioavailability of Arsenic in Soil

Another explanation for the minor impact of soil arsenic on body burdens of arsenic is that arsenic in soil has a relatively low bioavailability and is absorbed into the body (i.e., bloodstream) less efficiently than arsenic in water, the form used by U.S. EPA for the arsenic cancer slope factor. The bioavailability of arsenic in soil depends on two steps: solubilization in gastrointestinal (GI) fluids and absorption across the GI epithelium into the bloodstream (Valberg et al., 1997). Both the solubilization and absorption depend on a variety of factors including the chemical forms of arsenic, the mode of intake by the individual (with or without food, type of food), and the nutritional status, which affects the pH throughout the GI tract, and GI transit time.

The solubility of arsenic depends on soil particle size and the associated soil matrix materials. Particle size affects solubility because larger particles dissolve more slowly than smaller particles, hence, the percentage dissolved during GI transit time increases as particle size decreases. Solubility of arsenic may be limited when insoluble matrix minerals (e.g., quartz) encase arsenic compounds. Similarly, formation of iron-arsenic oxides and phosphates, and prevalence of authigenic carbonate and silicate complexes also limit the solubility of arsenic (Davis et al., 1992 and 1996). The solubility in the GI tract is complex since the pH conditions change from low pH in the stomach to a much higher pH in the small intestine. Readily soluble arsenic compounds, such as arsenate and arsenite, are more bioavailable than poorly soluble arsenic compounds, such as arsenic trioxide (ATSDR, 2000).

Several animal studies have evaluated the bioavailability of soil-bound arsenic. Results from Freeman et al. (1993 and 1995) and Groen et al. (1994) indicated that soil-bound arsenic is not as bioavailable as arsenic in solution. The bioavailability of soil arsenic relative to aqueous arsenic administered by gavage was approximately 20 percent in monkeys and 48 percent in rabbits. The higher relative bioavailability in rabbits reflected the higher absolute bioavailability in this species. This was much lower than the 64 to 69 percent of arsenic recovered in urine after ingestion of dissolved arsenic by human volunteers (Johnson and Farmer, 1991). Casteel et al. (1997) conducted a multi-year investigation of bioavailability of metals in soil and mine wastes using young swine whose GI system is more similar to humans than other animals. The relative bioavailability of arsenic in soils at various mining and smelting sites ranged from 7 to 52%, which agreed with the results of previous studies by Freeman at al. and Groen et al. Rodriguez et al. (1999) performed a similar swine study that reported the range of 2.7 to 42.8% relative bioavailability of arsenic in soil. Based on Gradient's literature review, a relative bioavailability of 50% is the maximum value reported in any of the peer-reviewed, published arsenic bioavailability studies. This evaluation used a relative bioavailability of 80%, based on guidance from USEPA Region 10. The relative bioavailability of 80% is thus likely to overestimate arsenic risks.

5.5.2.4 Cancer Slope Factor (CSF) for Arsenic

Reports on arsenic toxicity in humans are largely based on exposure to arsenic compounds in media other than soil, for example, consumption of drinking water and inhalation in occupational settings. USEPA has derived toxicity factors, *i.e.*, reference dose (RfD) and cancer slope factor (CSF), for ingested arsenic based on data from a Taiwanese study evaluating the health effects associated with the consumption of water containing high concentrations of arsenic (Chen *et al.*, 1985; Tseng *et al.*, 1968). Although the application of the population data used to derive the RfD and CSF has been heavily debated (Carlson-Lynch *et al.*, 1994; Smith *et al.*, 1995; Beck *et al.*, 1995; Mushak and Crocetti, 1995 and 1996; Slayton *et al.*, 1996), the values derived are generally believed to be conservative.

The CSF is based on skin cancer observed in a study of over 40,000 people in Taiwan who were exposed for a significant portion of their lifetime to elevated levels of arsenic in groundwater. Although the study clearly indicates an association between high levels of arsenic exposure and cancer, the study design limits its usefulness to derive precise dose-response relationships. The reasons are summarized below:

Exposure Assessment. There are considerable scientific concerns about the exposure estimates in the Taiwanese study (USEPA Region 6, 1998). Individual exposures were not characterized, and exposures were based on average arsenic concentrations of ground water in wells in each village. The amount of exposure was broadly classified into three groups (high, medium and low) and the original data were not available. The analytical method used to measure arsenic concentrations may not be accurate at low levels.

Human-to-Human Variation. In general, dose levels, genetic factors, dietary patterns, or other life style factors may alter arsenic metabolism and detoxification in different populations (USEPA Region 6, 1998). Taiwanese may be more susceptible than U.S. population, and therefore CSF based on Taiwanese population may overestimate cancer for U.S. population. The protein deficiencies in Taiwanese diets could affect their ability to methylate and therefore detoxify arsenic, leading to an increase in cancer risk. Consequently, extrapolation from one population to another becomes highly uncertain.

Other Sources of Exposure. When the U.S. EPA derived the CSF, they did not take into account other possible sources of arsenic in the Taiwanese diet (e.g., from rice and yams) and

dietary uses of drinking water. Hence, the assumptions used by the U.S. EPA in deriving toxicity values for arsenic underestimate the total arsenic intake, and as a result, the CSF may overestimate cancer risks.

Non-Linear Dose-Response. A recent U.S. EPA panel concluded that the dose-response for arsenic appeared to be non-linear (USEPA, 1997b), and the U.S. EPA Region 6 concluded that the available data "support a plausible threshold" (USEPA Region 6, 1998). The possible sublinear or threshold dose-response relationship suggests that cancer risk at low doses of arsenic may be less than predicted based on a linear model.

Arsenic Differs in Water and Soil. Health effects associated with arsenic in water may not be relevant to assess the toxicity in soil (Valberg et al., 1997). Arsenic exists in different chemical forms in water and soil, which may lead to potential differences in systemic bioavailability and dose-to-target organ. The relative proportion of overall arsenic intake and the correlation with urinary-arsenic concentrations may also be different between arsenic in water and soil. The differences will ultimately impact the overall potential for adverse health effects.

Overall, these uncertainties limit precise quantification of the dose-response relationship, but suggest the current CSF may overestimate cancer risks for a U.S. population exposed to lower levels of arsenic. Two recently published articles provide evidence that the CSF overestimates the cancer risk for arsenic as applied to drinking water studies outside the U.S. (Guo and Valberg, 1997) and within the U.S. (Valberg et al., 1998). These papers report a meta-analysis of epidemiological studies evaluating the skin cancer incidence of 29 populations in India, Japan, Mexico, Taiwan and the U.S. who were exposed to 1.17 to 270 µg/L arsenic in water. The authors evaluated the validity of U.S. EPA arsenic CSF model to predict the expected number of skin cancers by conducting a likelihood ratio analysis. This analysis showed that a null hypothesis of no additional skin cancer risk from arsenic was approximately two times more likely than the hypothesis of the predicted rate of skin cancer from arsenic. This analysis indicated that the CSF derived from arsenic exposure in the Taiwanese populations is likely to be an overestimate when applied to the U.S. populations.

Additionally, in the epidemiological studies of a U.S. population that has been exposed to arsenic in drinking water, no increased cancer rate has been observed (USEPA Region 6, 1998). This is further supported by studies of individuals exposed to arsenic in soil who thus far have not indicated any toxicity (Binder et al., 1987; Wong et al., 1992).

5.5.2.5 Summary of Arsenic Risks and Uncertainty

Any effect of arsenic in soil on total arsenic body burden is difficult to observe as a result of the commonly reduced bioavailability of arsenic in soil, and the extent to which soil's contribution to body burden is overwhelmed by background levels of arsenic in food and water. Coupling these considerations with the uncertainty in the derivation of the arsenic cancer slope factor suggest that an acceptable risk level for soil arsenic may be close to 10⁻⁴.

5.5.3 Uncertainties in Risk Characterization

Uncertainties associated with the first three steps of the risk assessment (data collection, exposure assessment, and toxicity assessment) are incorporated into the risk estimates in the risk characterization step. Although there are numerous uncertainties associated with this risk assessment, the incorporation of

25

a large number of conservative assumptions has yielded risk estimates that are likely to overestimate actual site risks.

203030

6 Soil Lead Cleanup Levels

Lead risks are unacceptable for the construction worker in the main facility area, and the groundskeeper and the future site worker in the grassy area. Therefore, soil lead cleanup levels were calculated for these areas.

A preliminary remediation goal (PRG) is the average concentration in an exposure area that will result in an acceptable risk to a particular receptor. PRGs are risk-based target cleanup levels that must be met *on average* throughout the exposure area. It is acceptable to leave concentrations that exceed the cleanup level, so long as the post-remediation *average* concentration does not exceed the risk-based cleanup level.

The Remedial Action Level (RAL) is the concentration above which soil must be removed, so that the post-remediation average concentration meets the specified target cleanup level (USEPA, 2001c). The RAL is a remedial action goal (i.e., a remediation trigger concentration) that ensures the post-remediation average concentration at a site achieves the target cleanup level with a specified level of confidence.

PRGs for lead were calculated for subsurface soil (0-5 feet) in the main facility area and surface soil (0-6 inches) in the grassy area (Table 7). In the main facility area, the PRG for lead in subsurface soil is 4600 mg/kg for the construction worker. In the grassy area, the PRG for surface soil is 3195 mg/kg for the future site worker.

RALs were calculated for these two receptors, assuming that excavated soil would be replaced with clean backfill containing lead at 50 mg/kg. The RAL for the main facility area is 78,900 mg/kg for subsurface soil. The RAL for surface soil in the grassy area is 16,700 mg/kg.

7 Conclusions

Cancer risks attributable to arsenic were calculated for receptors in three exposure areas. All of the calculated cancer risks fall within USEPA's target risk range of 1×10^{-6} to 1×10^{-4} . The exposure scenario with the highest excess lifetime cancer risk is the future site worker in the grassy area (4×10^{-5}) . The exposure pathway with the greatest contribution to cancer risk is soil ingestion.

Noncancer risks attributable to arsenic were calculated for receptors in three exposure areas. All of the calculated noncancer risks are below USEPA's target hazard index of 1.0, indicating that significant health effects are unlikely. The exposure scenario with the highest noncancer risk is the onsite construction worker (HI of 0.4). The exposure pathway with the greatest contribution to noncancer risk for the resident is soil ingestion.

Lead risks were evaluated for adult and/or adolescent receptors in three exposure areas. Lead risks were evaluated by comparing the predicted fetal BLL for each receptor to USEPA's BLL goal of $10 \,\mu\text{g/dL}$. Predicted 95^{th} percentile fetal BLLs exceeded USEPA goals for the construction worker exposed to subsurface soil in the main facility area, and the groundskeeper and future site worker exposed to surface soil in the grassy area. Lead in surface soil does not pose a significant risk for the offsite gas facility worker.

| Receptor | Chemicals Evaluated | Intake Factor (IF) | Soil Concentration (C) (mg/kg) | Dermal Absorption (A) | Daily Intake DI=C×IF×A (mg/kg·d) | Reference Dose (RfD) (mg/kg·d) | Hazard Quotient HQ=DI+RfD |
|-----------------------------------|------------------------|-----------------------|--------------------------------------|--------------------------|--|--------------------------------------|---------------------------------|
| Onsite Construction Worker | Arsenic | 1.29E-06 | 123 | 3.00E-02 | 4.77E-06 | 3.00E-04 | 1.59E-02 |
| Onsite Utility Worker | Arsenic | 2.58E-07 | 123 | 3.00E-02 | 9.54E-07 | 3.00E-04 | 3.18E-03 |
| Grassy Area Site Worker | Arsenic | 1.30E-06 | 312 | 3.00E-02 | 1.22E-05 | 3.00E-04 | 4.05E-02 |
| Grassy Area Landscaper | Arsenic | 1.29E-06 | 312 | 3.00E-02 | 1.21E-05 | 3.00E-04 | 4.02E-02 |
| Grassy Area Adolescent Trespasser | Arsenic | 3.53E-07 | 312 | 3.00E-02 | 3.30E-06 | 3.00E-04 | 1.10E-02 |
| Offsite Gas Facility Worker | Arsenic | 5.81E-06 | 28.5 | 3.00E-02 | 4.97E-06 | 3.00E-04 | 1.66E-02 |

Notes:

Daily Intake (DI) = Concentration (C) * Intake Factor (IF) * Dermal Absorption (A)

where:

IF = Intake Factor (AF * SA * EF * ED * CF) / (BW * AT)

AT = Averaging Time - Noncancer (d)

AT = Averaging Time - Cancer (d)

BW = Body Weight (kg)

CF = Conversion Factor (kg/mg)

ED = Soil Dermal Exposure Duration (yr)

EF = Soil Dermal Exposure Frequency (events/yr)

SA = Surface Area Exposed to Soil (cm²/event)

AF = Soil Soil/Skin Adherence Factor (mg/cm²)
